The Relations of Sarcoma, Prurigo, and Nævi to the Nervous System.—Professor Campana, of Genoa, relates facts that lead him to believe that sarcoma of the skin is intimately related to the nervous system (*The British Medical Journal*). He states that this affection is commonly accompanied by sarcoma and fibroma of the peripheral nerves, and that the nerves have a considerable influence in the spreading and reproduction of the disease in the skin. He insists that sarcomatous changes in the skin and nerves are found associated, and that the changes in the nerves often antedate those of the skin; that many vascular and lymph angiomata are distributed in the territories of certain nerves (Recklinghausen), and that many fibromata of the skin have relations to neuromata and fibro-neuromata; that a form of sarcoma of the skin which he described had appeared symmetrically like an exanthema, in the manner of various erythemas which are at present accepted as of nervous origin (Lewin), and which frequently correspond to the peripheral distribution of certain nerves. He calls attention to the fact that, in the neoplasm, all the elements in the growth are not sarcomatous cells, and, further, that in places in which there is special accumulation of indifferent cells, nerve terminations with sarcomatous swellings are found. He has made the observation that recurrent nettle-rash or itching in the extremities frequently precedes sarcoma, and that these are symptoms which can only be ascribed to the nervous system; that there is severe pain in the course of the nerves which lead to the affected parts, especially on pressure; and that in these forms of sarcoma a period of hyperplasia and a period of atrophy can be observed, an atrophy without ulceration, which is rare in other forms of sarcoma. Campana considers that the first localization takes place either in a tumor of the skin or in a tumor of another organ. Thence there is localization in the nerves that are in connection with it, and, through the medium of the nerves, development of tumors in other parts of the skin. In another section of the same paper Campana discusses the nature of the changes that cause prurigo, the pathology of which he assigns to the nervous system, although he remarks that inflammatory affections of the nervous system are common, whilst cases of prurigo are rare, and that every neuritis is not accompanied by itching. In this connection he points to the fact that, in a case of multiple fibro-sarcomatous neuritis, the prominent symptom was neither anæsthesia nor hyperæsthesia, but itching. In prurigo he has found changes in the peripheral terminations of the nerves, and has seen that many of the nerves of the skin in subcutaneous tissue have lost their form, and are much thicker than in normal conditions. He has observed that on the parts where these changes are found, even in a dead body, the skin was observed to be rough, scaling, and pigmented in small spots. In this connection he refers to a case in which sarcomatous changes in the nerves were not preceded, but followed, by itching, and in which afterwards changes took place in the skin which were suggestive of prurigo. In the same paper, in a section on nævi, Professor Campana states that he has a record of fifty cases in which the distribution of nævi showed unmistakably their relation to the nervous system. He considers that changes in such cases should be looked for not in the nerve-centres, but in the peripheral nerve branches.

CONSTIPATION IN INFANCY.—In those cases which do not recover under proper dietary management, Dr. Eustace Smith recommends :

℞. Tinct. nucis vom .... ♏ ss.
Tinct. belladonnæ .... ♏ x.
Infusi sennæ .... ♏ xv.
Infusi calumbæ.................ad ʒ j.

This may be given thrice a day at first. After a time, two doses will be enough ; and before long, one dose at bedtime. An equally good or better prescription is :

℞. Tinct. nucis vom................ ♏ ss.
Ext. cascaræ sagradæ liq......... ♏ xx.
Tinct. belladonnæ................ ♏ x.
Inf. calumbæ....................ad ℥ j.

The keynote is the combination of nux vomica with belladonna and some gentle laxative. Dr. Eustace Smith also recommends, where the motions are very dry, a saline aperient :

℞. Quiniæ sulph.................. gr. ¼
Acid. sulph. aromat .... ♏ j.
Tinct. nucis vom................. ♏ ss.
Aquæ .... ad ℥ j.

This for a child of six months.

INFECTION OF FŒTUS THROUGH PLACENTA.—The precise manner in which the fœtus is infected by a disease which has attacked the mother has often been disputed. Small-pox, tuberculosis, and syphilis may infect the fœtus. If these diseases depend on micro-organisms, these germs must pass through the placenta; if so, the placenta is not a filter which arrests all solid or noxious bodies, as an old theory supposes. If it be a filter, how is it that, as experience has proved, it does not always let the same micro-organism pass? This is the case with charbon in rabbits. And how is it that the placenta always gives transit, on the other hand, to certain specific micro-organisms, as in the case of chicken-cholera? These questions have been propounded in the *Archives de Tocologie* for August. They appear to be solved by certain experiments conducted by M. Malvoz, of Liége, recapitulated in that periodical. M. Malvoz contends that micro-organisms only clear the placental barrier and enter the fœtus when the placenta itself presents pathological changes in its chorionic villi, changes generally due to the micro-organisms themselves Thus Malvoz injected into the blood of pregnant rabbits emulsions of Indian ink, an inert substance, and into others solutions containing non-pathogenic bacilli. In no case were any granules of the ink or any bacilli found in the fœtus, and in all far less of the infected substances were detected in the placenta than in the liver of the mother. After similar infections with bacillus anthracis, the tissues of 32 fœtuses were subjected to cultivation, but, in 163 tubes of cultivating fluid, only 4 showed the charbon bacillus. Lastly, M. Molvoz inoculated pregnant rabbits with chicken-cholera. In every case the specific bacillus was found in the fœtal tissues. On examining the placentæ in the latter case, they were invariably found to be diseased; in the charbon experiments the placentæ were but rarely diseased; in the Indian ink and non-pathogenic bacilli cases the placenta was never diseased. The placenta was diseased in all the few cases where the charbon bacillus infected the fœtus. The germs were found abundantly in hæmorrhagic areas disseminated over the placenta. Clinically, placental lesions are found in syphilis and small-pox, diseases often communicated to the fœtus. Thus it would appear that the placenta allows the transit to the fœtus of those micro-organisms only which have the property of first setting up morbid changes in its own substance.—*The British Medical Journal.*

SARCOMA OF THE BLADDER.—Dr. Southam thinks that sarcoma more commonly affects the bladder than is generally said to be the case, and that such growths are usually primary. They are most common at two periods of life, viz., under ten and between forty and seventy. Males are more commonly affected than females. The growths usually originate in the connective tissue of the submucous layer and are most often met with at the face or on the posterior wall. They are often multiple, especially in children. The surface of the growths may or may not be villous in character, and the tumors usually remain confined to the walls of the bladder. Secondary deposits in other parts of the body are more frequently absent than present. Evidences of chronic cystitis are found, as a rule, in the bladder structure. Secondary changes in the kidneys are after a time usually produced, either in the form of distention from ureteric obstruction, or from pyelitis. Secondary deposits are rarely seen in the kidneys. The general symptoms are those of hæmaturia with vesical irritability. In discussing leading signs in detail, Mr. Southam says that hæmaturia is a prominent and often an early symptom. It frequently precedes the signs of irritability, sometimes it comes on at the same time, and occasionally it follows afterward, and cases are recorded where it has been altogether absent. Micturition becomes more painful and frequent as the disease progresses. Sudden stoppages sometimes occur when the tumor is pedunculated and is drawn over the vesical outlet. Only when the tumor is of firm consistence can we obtain evidence of its existence by digital examination from the rectum or by careful sounding. Microscopic searching of the urine for small detached pieces of the growth is of the greatest possible value. A diagnosis of sarcoma from papilloma or cancer is often quite impossible. Untreated cases sooner or later terminate fatally in a period from one to four years. With regard to treatment, Mr. Southam argues that as palliative measures are of little use, the bladder should be explored and an attempt made to remove the growth with forceps, scraping, or écraseur. He gives preference to the suprapubic incision, because of the free access it gives to the whole interior of the bladder cavity. Speaking of recurrence after removal, he says this is to be expected, especially when the growth is sessile and infiltrates the walls. The results of operative interference show that life is undoubtedly prolonged and symptoms much relieved. Whether permanent cure is ever to be obtained, future observation can alone determine.—*Birmingham Medical Review*, October, 1888.

CHRONIC VOMITING RELIEVED BY ABDOMINAL SECTION AND THE BREAKING DOWN OF ADHESIONS OF THE PYLORIC END OF THE STOMACH AND OF THE DUODENUM.—Professor Loreta has reported the following case, which demonstrates anew that heroic surgical measures do not always lead to a cure, even if the immediate operation is "successful." The case is published in full in the *Gazzeta degli Ospitali*, and the *London Medical Recorder*, October 20, 1888, adverts to it as follows: The subject of the operation was a young woman, twenty-two years of age. She had a family history of phthisis, and had suffered from enteric fever at the age of sixteen. The gastric disturbances commenced five years ago, that is, about a year after the fever. At first they were limited to a sense of fulness and some pain at the epigastrium after meals, followed by eructation, and occasionally (every three or four days) by vomiting. She gradually became worse. The pain was continuous, and chiefly in the region of the pylorus. Vomiting took place about half an hour or an hour after every meal. The vomited matter was partially-digested food, and presented no peculiarity. There was never any admixture with blood. On examination of the epigastrium succussion could readily be obtained, and there was some increased resistance in the region of the pylorus. Frerich's effervescing mixture was given, and the stomach, becoming distended with gas, was easily mapped out. The cardiac end and the greater curvature were readily distinguished, but the pyloric end could not be clearly defined. It was evident that there was no considerable dilatation. The vomiting was unchecked by medicines, nor was it in any way influenced by dieting. It was decided that carcinoma, gastric ulcer, chronic gastritis, and nervous vomiting could be excluded, and that the diagnosis lay between stenosis of the pylorus and adhesion of the stomach to the surrounding viscera preventing the free peristaltic movements, and so interfering with the pressure that is normally put on the contents of the stomach to force them through the pylorus. It was felt that either of these conditions could only be relieved by an operation, which was, consequently, performed under chloroform. An incision, five inches long, was made from an inch below the ensiform cartilage downward, and to the right. The liver presented itself in the wound, and when it was pushed upward out of the way, an attempt was made to bring the stomach into the opening. This was found at first to be impossible, on account of extensive adhesions. After much trouble some of these were broken down, a small opening was made into the stomach, and a No. 8 catheter passed through the pylorus. Using the catheter as a guide, the finger was subsequently passed through the pylorus, which was found to be quite free. The remaining adhesions of the stomach and of the duodenum were now torn through, the opening in the stomach stitched up by continuous suture, and the abdominal wound closed. There had been very free venous hæmorrhage from the torn adhesions, but this was disregarded, the blood being allowed to remain in the peritoneal cavity, and no special means being used to check the hæmorrhage. The reason for this unwonted procedure is explained in the following theory, put forward by Professor Loreta, but which will not gain general acceptance. Hæmorrhage from the liver, or venous hæmorrhage generally within the abdomen, is not fatal, either by the quantity of blood poured out, or by the influence which the latter exercises on the peritoneum, which actively absorbs the blood, and restores it to the circulation. Notwithstanding this theory, the patient was very collapsed after the operation, and was only revived by the subcutaneous injection of ether, and the application of warmth to the extremities. She recovered from the operation, but, some months later, all the old symptoms and the vomiting returned.

Silver Poisoning from the Prolonged Application of Caustic.—Dr. Svonnikoff mentions a case of argyria, following constant applications of lunar caustic to the throat. The patient was a peasant woman, fifty-three years of age, who had had syphilis sixteen years previously. She was treated by frictions and applications with the brush of a fifty per cent. nitrate solution of silver to the throat for several weeks, she herself using the brush whenever the throat was painful. The pharynx, the hard palate, the gums, and the upper part of the chest and back became stained a deep-gray color, and the discoloration was even more marked on the face. A similar case has been reported by Dugiel.—*The British Medical Journal.*

The Treatment of Club-foot by Immediate Restoration of the Parts to their Normal Position after Tenotomy.—Discussion has letely taken place as to the best and safest method to be used in the cases of talipes. Mr. Walsham, as surgeon to the orthopædic department at St. Bartholomew's Hospital, gives his experience. He originally employed the slow method, but was dissatisfied with the delay and difficulty in obtaining the expensive appparatus necessary for this method. By slow degrees he reduced the foot to a greater extent after the operation, and, meeting with no untoward results, finally reduced the deformity immediately. His method is to divide the tendon; break down any adhesions by forcible but gentle wrenchings; close the puncture with a dossil of lint soaked in carbolic oil or iodoform gauze; carefully enclose the foot in a domett or cotton-wool bandage according to the age of the patient, and secure it in plaster of Paris. The plaster is left on for ten days or a fortnight unless any special reason is seen for removing it earlier. He claims for this operation the following advantages over the slow method: (1) Great saving of time; (2) the doing away with the necessity of an expensive extension-apparatus. The disadvantages attending the rapid, but not applying to the immediate method are: (1) Considerable pain is often caused by the force which has to be employed in stretching the uniting material at each changing of the plaster, and (2) that in severe cases the reparative material cannot always be stretched sufficiently to overcome the deformity, and it is occasionally necessary to divide the tendon.—*The Annals of Surgery.*

Bloodless Methods of Treating Ingrowing Nail.—Dr. Patin recommends the following procedure for removal of ingrowing toe-nail, which he has employed with excellent results in many cases. After thorough cleansing of the nail, a solution of gutta-percha ten parts, in eighty parts of chloroform, is applied with a brush to the interstices between the nail and the granulations. This is repeated several times on the first day, and subsequently at longer intervals. By exercise of care and patience it will be found that the nail is gradually lifted from the underlying parts, and can then be removed without pain with the scissors. If a properly fitting shoe is worn, no recurrences need be apprehended. The solution applied in this manner exerts a double effect, the chloroform is an anæsthetic, and the gutta-percha acts mechanically, forcing its way between the granulations and the nail, and finally liberating it from its abnormal position. Another method is described by Dr. Hoffman, as follows: "The toe is first thoroughly washed with an antiseptic solution. A few drops of liq. ferri. chloridi are then applied to the granulating surface, the nail slightly raised, and the solution allowed to dry. After two to three days the scab is removed, and the application of the solution repeated. In a few days the edges of the nail become brittle and can be cut away with a fine scissors or blunt knife. To prevent a return of the trouble thin shavings of cork are inserted under the nail-border."

Inhalations in Phthisis.—Dr. C. T. Williams has found antiseptic inhalations useless *quâ* antiseptic action. Carbolic acid has sometimes a useful effect by its anæsthetic action, but any means which dulls the sensibility of the mucous membrane ought to be used with great care; there are greater dangers in bronchitis, especially of old persons, than a considerable cough and expectoration. Most of the drugs used either had no effect or acted better given by the stomach. Turpentine may possibly be an exception; at any rate it is readily absorbed and quickly appears in the urine. In the treatment of hæmoptysis and chronic bronchitis there are few drugs which equal turpentine. In hæmoptysis inhalations are good (℥ ss.) repeated frequently. In the subacute exacerbations of chronic bronchitis turpentine often works wonders, especially if preceded by nauseating doses of ipecac. This is old-fashioned pharmacy, but I find that a great many, like myself, after trying all sorts of new-fangled dodges and drugs, fall back on the old plan.

Arsenic in Rheumatoid Arthritis.—Dr. Osler recommends Fowler's solution in initial doses of five drops three times a day in the treatment of rheumatoid arthritis. This dose is gradually increased to the limit of tolerance and then held there, the effects of the drug being carefully watched.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 24, 1888.

MEDICAL EDUCATION AND LEGISLATION.

WE think few will deny that legislation is in itself more or less of an evil, albeit a necessary evil, and that the less there is of it in a community, over and above what is absolutely needed for the protection of society, the better off that community is. The more freedom a people enjoys, the happier it is, and the tendency of law is to restrict the freedom of the individual, although it may be for the best interests of the greater number. This is as true in regard to matters concerning the medical profession as it is in other things. Theoretically, every person should be as free to give advice to the sick, if he so desires, and if the sick one seeks advice from him, as he is to build a house. If the sick, the opponents of medical legislation say, are willing to intrust their lives to the care of any individual, they should be allowed to do so, whether the person selected be presumed to be a competent physician or not. It is a matter that concerns only the patient and his medical adviser, and the State has no right to step in and say whom he shall or shall not employ in that capacity.

But the State does interfere in the matter of housebuilding. It does not, it is true, prescribe certain qualifications without the possession of which no one shall be allowed to lay bricks or join timber, but it passes judgment on the completed work. It recognizes that an insecurely built house is a menace to the lives of those who dwell in it, and it condemns the structure so erected. By establishing a standard to which the finished work must conform, it practically ordains that none but competent workmen shall have a hand in its construction. But in medicine the case is different. The State cannot judge of the results, except in a few most evident cases of malpractice, for it is manifestly impossible to set up a certain criterion of health by which to gauge the skill of the physician. It is obliged, therefore, if the lives of its members are to be protected, to establish a standard for the physician himself, and to forbid all who do not conform to that standard to take upon themselves the responsibilities of medical practice.

There is an element of selfishness, possibly, in the demand of the profession for laws regulating the practice of medicine, for such laws might tend to lessen competition by shutting out the quacks; yet that that is not the real motive for their request must be admitted by all fair-minded men. None knows so well as the educated physician what a power for evil the ignorant and unskilled practitioner is, and it is solely for the protection of the community that legislation of this nature is sought. If a child does not know enough to keep away from what is liable to do him harm, he must be restrained by others who are wiser than he, and if the members of a community are incapable of selecting a competent medical adviser, they must be prevented from selecting an incompetent one.

This much will probably be conceded by most men, but another difficulty presents itself in deciding who are to be regarded in the eyes of the law as competent physicians. Are only regular physicians to be allowed to practise the healing art, or is the same privilege to be granted to homœopathists, eclectics, faith-healers, Christian scientists, herb doctors, and all other irregulars? Manifestly the State cannot discriminate between two educated physicians, one of whom adheres to scientific methods and the other calls himself a follower of Hahnemann; and if not between them, how can it do so between a faith-curer and an herb doctor, if both give proof that they are thoroughly grounded in the principles of medicine, and differ only in their therapeutic methods? This is a real difficulty, and one that cannot be overcome, but it should not discourage us from doing what we can in the way of securing medical advisers who are well grounded, at least, in the principles of their art. The only feasible way of getting round the difficulty, for the present at least, is to ignore the question of therapeutics while insisting upon a thorough knowledge of all the other branches of medical science.

In a paper read before the American Social Science Association, September 5, 1888, which has been the occasion of these reflections, Mr. W. A. Purrington proposes a scheme of legislation for promoting a more thorough medical education, by refusing the right to practise to all who are unable to give evidence of possessing the proper mental equipment for such work. He suggests that the licensing power be vested in a central Board of Medical Examiners, and that the law prescribe regulations governing the admission of applicants to the ranks of the medical and allied professions. The examinations shall be held on all the branches of medical study except therapeutics, the author holding that one who should prove himself to be thoroughly grounded on these subjects, and to be educated in a true sense to observe and draw sound deductions from observation, might well be trusted to form his own conclusions and pursue his own studies as his judgment should dictate in the science of therapeutics.

This is, perhaps, the best that could be done under present circumstances, although it can hardly be regarded as entirely satisfactory, for a good education in one branch of science does not necessarily imply that its possessor will exercise common sense in drawing his conclusions concerning another branch. A man might be an excellent pathologist and diagnostician while holding the most heretical and absurd views of therapeutics. Nevertheless, some legislation on the lines laid down by Mr. Purrington might be most beneficial. The Illinois State Board of Health has effected much good in this direction, although there is still room for improvement, and something of a similar nature might well be expected to accomplish good results in this State. Even our present registration law is an improvement on no law, and the practice of medicine might be restricted still further before it could be maintained that the liberties of the people were being unjustly curtailed.

THE FOOD OF AMERICAN AND EUROPEAN LABORERS.

Professor W. O. Atwater, of Wesleyan College, has been lecturing on food economics, and claims to have data which show that the American laborer, by reason of better food, does more work per day than the European laborer. Food is force in potential form. Its amount may be measured in calories or heat units, and a day's food for a healthy man should be sufficient to furnish 2,500 to 3,000 calories. The dietary of the European laborer, we are told, rarely furnishes 2,500 calories; while that of the American furnishes from 3,000 to 5,000 calories.

The data for demonstrating that American laborers of all classes do more work because they are better fed must be very considerable, in order to satisfy critical examination. It has been abundantly shown that hard labor cannot be performed on an insufficient diet; but it is also known that a sufficient diet is not a difficult or expensive thing to get. A working-man must have a little over 20 grammes of nitrogen, and 300 grammes of carbon, daily, with water, and the latter practically costs nothing. A half a pound of meat or cheese, with a pound and a half of bread and butter, or farinaceous vegetables, furnishes all the calories needed. And because the American laborer has meat twice daily and plenty of vegetables, it does not follow that he can work more.

Just as much work can be done on a sufficient diet as on an excess. As for the class of laborers who are furnished with daily food representing 5,000 calories, representing six or seven pounds of meat daily, they must be highly fed and enviable persons; but whether they can do more work because their diet contains 5,000 calories of potential energy may be questioned.

DEATH BY ELECTRICITY.

The special method for executing criminals by electricity has been studied by a committee of the Medico-Legal Society, with results that leave still in doubt the question whether the new law is a wise one.

The plan suggested by the committee consists briefly in pinioning the prisoner to a table or chair. One small electrode covered with sponge, is fastened to the top of the head, the other to the spine between the shoulders. A current of at least 3,000 volts is then passed through the victim for thirty seconds.

Most persons who have been killed by powerful electrical currents have been severely burned, and even disfigured. It is not impossible that a 3,000-volt current of thirty seconds duration would produce severe cauterization in the region of the electrodes.

There is little doubt that so powerful a current applied in the way indicated will kill a man. But it does not seem much more humane, or civilized, or even scientific, to strap a condemned prisoner to a chair and throw him into a convulsion, or possibly burn the top of his head off, than to have him neatly despatched by strangulation or the guillotine.

News of the Week.

The Death of Dr. Sands leaves New York without a surgeon of such pre-eminence as to entitle him to be called the leading surgeon of the city. There are plenty of admirably equipped and skilful men, surgeons of as great promise or attainments perhaps as our late lamented colleague. But the time of men who attain such striking and extraordinary surgical skill as to place them far above the plane of their brother-workers seems to have passed. This means, probably, only that the very best surgeons are more numerous than they used to be.

Dr. N. S. Davis is reported to have resigned his position as editor of the *Journal of the American Medical Association.* Dr. John B. Hamilton, Surgeon-General, United States Marine Hospital Service, has been elected in his place.

We receive at Intervals communications from country practitioners, enclosing the circulars of a so-called "infirmary" or "maternity home." Its objects are to furnish opportunities for single women who have become pregnant to be confined. "Superior accommodation," "strict privacy," and the attendance of a skilful physician are promised. Last year it is said that over fifty thousand of the circulars advertising this place were sent out to physicians all over the country. It is hard to find language strong enough to fitly condemn this abominable trading in the misfortunes of women. There is, however, so far as we know, no means of stopping it.

A New Academy Building.—We have received a number of communications warmly supporting the views expressed by us a week ago with regard to a new building for the New York Academy of Medicine. There is a wide-spread feeling that something should be done promptly, and that plenty of money will come in when there is something in actual existence on behalf of which the public can be appealed to.

Antipyrin and Belladonna.—A correspondent writes, asking if there is a physiological antagonism between antipyrin and belladonna. Prescriptions were given to two patients suffering from whooping-cough. One contained antipyrin, gr. xx., tincture belladonna, ♏ v. The other contained fifteen grains of antipyrin and five drops of tincture of belladonna. The patients, who were adults, both suffered severely from great respiratory oppression, sensations of cerebral pressure, and intense discomfort and fright. Both had at various times taken antipyrin before, in large doses, without feeling bad effects.

American International Congress of Medical Jurisprudence.—The Medico-Legal Society of New York will hold an International Congress of Medical Jurisprudence, which representatives from other countries will be invited to attend. The Congress will last four days, and will meet next year, but neither the place nor the exact date have yet been fixed. A sub-committee, consisting of Moritz Ellinger, Esq. (Chairman), Clark Bell, Esq., Dr. Isaac Louis Peet, Dr. Stephen Smith, Judge Noah Davis, and E. W. Chamberlain, has been appointed to make the necessary arrangements

Sulphonal, according to Dr. Max Engelmann, sometimes causes a scarlatinous eruption.

CONSULTATION BY CABLE.—In a recent serious illness of a patient stopping in British Columbia, Sir Andrew Clark, of London, was consulted. Wires were arranged so that there was direct communication from London to New York, and thence to the patient. For three hours he examined and advised regarding his transatlantic patient's condition. This is a very remarkable achievement of modern science, but we should prefer a sensible and experienced physician near by to the most eminent doctor in the world five thousand miles away.

THAT NINE THOUSAND.—It is estimated that in the last decade about nine thousand improperly educated doctors have been graduated from the medical schools. This makes nearly one thousand poorly educated and inadequately prepared physicians who are turned upon the public every year! We have already given the facts upon which the above estimates are based, viz., the examinations of the Virginia Board. Dr. Wood writes, in the *Therapeutic Gazette:* "From 1877 to 1887, inclusive, thirty-six thousand and ninety-seven graduates from medical colleges have entered practice in the United States. If these had all been efficiently examined according to the results just given, eight thousand three hundred would have been rejected, or about one-fourth the number. Our own opinion is that this proportion of rejections is less than it ought to be. We have gone over the class-books of the Medical Department of the University of Pennsylvania, and find that one-third of those who entered that institution failed to get their degree. Practically all of these people graduate at one college or another, and our own belief is that at least twenty per cent. more go through the University examination than ought to. Can any one estimate the amount of damage that nearly nine thousand improperly educated doctors can do in ten years?"

A SUCCESSFUL OPERATION.—Sir Henry Keating, the eminent judge, whose death at the age of eighty-four took place last week, owed the whole of his judicial career to a successful surgical operation; he survived the performance of ligature of the external iliac artery for femoral aneurism for nearly thirty years. The operation was performed by Sir William Ferguson in 1859, while Sir Henry Keating was Solicitor-General, and it was mainly owing to his illness that he accepted a puisne judgeship, an office entailing no fatigue of standing.

THE SALE of Sir Morell Mackenzie's book is said to have reached nearly 100,000 copies in the first fortnight of its issue. We are informed that the Empress-Queen Frederick has sent the author a long autograph letter expressing her complete approval of the manner in which he has performed his difficult task, and confirming some of his statements by her own independent knowledge.

DR. D. HAYES AGNEW.—It is stated that Dr. Agnew, Professor of Surgery in the University of Pennsylvania, is about to retire from the chair which he has so long filled.

ANOTHER MAD KING.—Reports are circulated that King Milan, of Servia, is insane or on the verge of insanity, as the result of heavy drinking and other forms of debauchery.

A NATIONAL LABORATORY AT WASHINGTON.—Dr. Frank S. Billings, of Lincoln, Neb., sends us a copy of a bill which it is proposed to introduce into Congress at its next session. It has the following features: 1. The bill divides the work into two distinct divisions, human and animal diseases, and thus at once creates a point of noble rivalry between them. 2. It places it in charge of the Surgeon-General of the Marine Hospital Service, thus supplying him with the means of acquiring a body of competent workers, with whom he may become acquainted beforehand. 3. It gives him the world to choose from for Directors of the two institutes, while it limits the selection of assistants to this country, thus providing the way of Americans of ability to rise to chief positions. 4. It gives a chemist to each institute, thus keeping up the stimulating rivalry. 5. It opens the way to independent workers, and thus increases the number, while the country has the benefit of the results. 6. It opens the way for students, thus providing the means for Boards of Health and Medical Schools to obtain competent men, and stimulating research in all parts of the country. 7. It tends to make our national capital a centre of learning and culture, which should be the ambition of every citizen.

A NATIONAL BOARD OF HEALTH.—At a meeting of the Councillors of the Massachusetts Medical Society, held October 3, 1888, the following resolves were unanimously adopted: "That in the opinion of the Councillors of the Massachusetts Medical Society the present epidemic of yellow fever, in several States of this Union, has again made evident the imperative need of some organization on the part of the General Government for the protection of the public health—an organization that shall be independent of existing bureaus, and solely devoted to this most necessary function of any form of government. That this resolution be sent to the President of the United States, to Members of Congress, and to the Boards of Health of the several States."

YELLOW FEVER.—The Jacksonville bulletin of November 19th showed that there had been 4,621 cases up to date, with 402 deaths.

ASSOCIATION OF ACTING ASSISTANT SURGEONS OF THE UNITED STATES ARMY.—We are requested to publish the following: An Association of past and present Acting Assistant Surgeons of the United States Army has been formed for the purpose of securing, so far as possible, a correct history of those who have served in this capacity, and also for mutual protection and benefit. The Association desires to obtain a complete list of all medical men who have served as Acting Assistant Surgeons in the United States Army, and, so far as possible, their complete medical history, date and place of birth, date and place of graduation, date of appointment, medical service and stations, list of contributions to medical literature, inventions, etc., date of termination of service, professional positions held in civil life, present residence and address. All information from friends concerning deceased Assistant Acting Surgeons will be gratefully received. All past and present Acting Assistant Surgeons are cordially invited to become members of the Association. The badge of the Association is the Geneva Red Cross. The enrollment fee is $1. The necessary blanks will be forwarded upon application. W. THORNTON PARKER, M.D., *Recorder A. A. A. S.*, Newport, R. I.

THE AMERICAN MEDICAL ASSOCIATION meets at Newport, Tuesday, June 25, 1889. The committee of arrangements consists of H. R. Storer, Chairman ; C. F. Barker, M. E. Baldwin. C. A. Brackett, J. P. Curley, P. F. Curley, J. P. Donovan, H. Ecroyd, Jr., V. M. Francis, T. A. Kenefick, G. M. Odell. F. H. Rankin, W. C. Rives, Jr., S. H. Sears, W. S. Sherman, H. E. Turner ; W. Thornton Parker, Local Secretarr.

THE INTERCOLONIAL MEDICAL CONGRESS.—Next year there will be an exhibition at Melbourne celebrating the centennial of Australia. At this time an Intercolonial Medical Congress will meet, and preparations for it are being made on a large scale. We learn from Dr. H. B. Allen, General Secretary of the Congress, that the Royal Mail Steamship Company will grant passages to members at twenty per cent. discount, and on arrival visitors will be furnished with free passes over the railways. It will be, therefore, a favorable opportunity to see the newest world. Of the meeting, Dr. Allen writes that it will take place at Melbourne, January 7, 1889, and that all that is representative in Australian medicine will be gathered there. At the inaugural meeting the President, Mr. T. N. Fitz Gerald (author of the article on Hydatids in Heath's "Cyclopædia of Surgery"), will deliver the inaugural address, and speeches will be made (we expect) by His Excellency the Governor, and by the Premier of the Colony. Subsequently addresses will be given by the presidents of the nine sections into which the Congress will be divided. Thus in the Section of State Medicine, Dr. Mac Laurin, the Medical Adviser of the Government of New South Wales, will describe the difficulties in the way of Sanitary Administration in these Colonies. In Psychological Medicine, Dr. Manning, Inspector of Asylums in New South Wales, will deal with the Curability of the Insane, and with Sporadic Cretinism. In the Section of Pathology, Dr. Bancroft, of Brisbane (of the Filaria Bancrofti), will submit his general experience in parasitic disease. In Pharmacology, Baron F. von Mueller, K.C.M.G., will deliver the address. Numerous papers will be submitted in all the sections. A special congress museum is being prepared. General discussions will be held concerning hydatid disease, fevers in Australia, Australasian climate, etc.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION meets at Birmingham, Ala., December 4, 5, and 6, 1888, Dr. W. D. Haggard, of Nashville, Tenn., presiding. The following is a partial list of the papers to be read : "Gastrostomy," by W. B. Rogers, M.D., Memphis, Tenn.; "Superinvolution of the Uterus following Trachelorraphy," by Virgil O. Hardon, M.D., Atlanta, Ga.; "Indications for Operative Interference in Cerebral Troubles," by T. O. Summers, M.D., Jacksonville, Fla.; "A Case of Tubal Pregnancy, presenting Interesting Medico-Legal Relations," by E. P. Sale, M.D., Memphis, Tenn.; "The Extravagancies and Impractical Requirements of Modern Antiseptic Surgery, so far as the Country Practitioner is Concerned," by J. M. Taylor, M.D., Corinth, Miss.; "Antiseptics in Surgery and Gynecology," by F. T. Meriwether, M.D., Asheville, N. C.; "My Antiseptic Bags; or, Practical Aseptic Surgery," by J. W. Long, M.D., Randleman, N. C.; "Floating Kidney, with Vicarious Menstruation," by DeSaussure Ford, M.D., Augusta, Ga.; "New Treatment of Intra-uterine Fibroids," by E. J. Beall, M.D., Fort Worth, Tex.; "The Medical Treatment of Fibroid Tumors of the Uterus," by Bedford Brown, M.D., Alexandria, Va.; "Alexander's Operation," by W. L. Nichol, M.D., Nashville, Tenn.; "The Present Status of Electro-therapeutics in Gynecology," by J. T. Wilson, M.D., Sherman, Tex.; "Surgical Tuberculosis," by W. Locke Chew, Birmingham, Ala. Adjournment at 1.30 P.M. Afternoon session at 3 P.M. "Treatment of Certain Forms of Menorrhagia, with Report of Cases," by W. D. Bizzell, M.D., Atlanta, Ga.; "Electrolysis in the Treatment of Urethral Strictures," by S. M. Hogan, M.D., Union Springs, Ala.; "Operative Procedures in Hypertrophy of the Prostate," by R. D. Webb, M.D., Birmingham, Ala.; "Electrolysis in Morbid Alterations produced in the Prostate by Gonorrhœa of the Urethra," by J. D. S. Davis, M.D., Birmingham, Ala.; "Dermoid Cysts of the Coccygeal Region," by E. J. Beall, M.D., Fort Worth, Tex.; "Hysterectomy in Cancer of the Uterus," by W. H. Wathen, M.D., Louisville, Ky.; "Fractures of the Fore arm," by John Brownrigg, M.D., Columbus, Miss.; "Treatment of Fractures with Plaster-of-Paris Splints," by W. F. Westmoreland, Jr., M.D., Atlanta, Ga.; "Interesting Cases of Surgery," by R. M. Cunningham, Pratt Mines, Ala.; "The New Departure in Uterine Therapeutics—The Dry Method," by T. A. Means, M.D., Montgomery, Ala.; "A Study of the Various Methods of Treatment of Laceration of the Perineum, and Rectocele, with Report of Cases," by J. H. Blanks, M.D., Meridian, Miss.; "Perineal Lacerations," by M. C. Baldridge, M.D., Huntsville, Ala.

THE MACKENZIE CONTROVERSY.—Our esteemed contemporary, *The Evening Post*, expends itself in a silly tirade against Sir Morell Mackenzie and his recently-issued book. Ignoring entirely the questions of fact and of justice in the case, the editorial writer thinks of, and deals with, nothing but the question of the propriety of publishing the work as Mackenzie did, and of the personal issues brought up in it. While all this is to be most seriously regretted and deplored, something must be granted to the natural instincts of anger and revolt when a man has been scurrilously attacked. We would invite the attention of our contemporary to an article in the *Nineteenth Century*, by Mr. R. E. Prothero, on "Frederick the Third and the New Germany." The writer is endorsed by *The British Medical Journal* as a writer "who has throughout been in a position to obtain the most authentic information, and is able to express the views entertained by those devoted friends who surrounded the late Emperor during his last illness. After a masterly analysis," says *The Journal*, "of the false issues raised in the 'official' report, Mr. Prothero discusses the true issue, which has already been put forward with admirable clearness in the letter of the Empress Frederick, which was published in the *Daily News* of October 12, 1888." That document refers to May, 1887, when the radical treatment was first proposed. "Mr. Prothero, who speaks as a layman well informed of the views held by the late Emperor himself, presents what he believes to be the *true* issue between Sir Morell Mackenzie and his German colleagues, as follows :

"In May, 1887, two German doctors, without special skill in diseases of the throat, unsupported by any pathological evidence, trusting to the infallibility of their diagnosis, and concealing from their patient and his family the nature of the proposed radical treatment, advised an external operation, which in 27.2 per cent. of the cases results in immediate death, which in 54.54 of the cases hastens death, which nearly always destroys the voice, and which in only two cases (and in one of those Dr. Lennox Brown doubts the existence of cancer) has effected a complete cure. The *Kölnische Zeitung*, commenting upon the proposed operation, remarks with complacent frankness; 'Death consequent on the operation would have been easy, nay, almost painless.' Against this proposal Sir M. Mackenzie took up a position from which he never swerved a hair's breadth. Without asserting an opinion whether the growth was or was not malignant, he maintained that no external operation was justifiable without pathological evidence of the existence of cancer; and that, even if cancer were thus proved to exist, a palliative treatment, which prolonged life under normal conditions of health for at least a year, and for another year under less favorable conditions, was to be preferred to a radical treatment. When the alternatives are so terrible, the patient must himself determine. In November, 1887, the Crown Prince deliberately refused to run the immediate risk of the external operation, with its remote possibilities and miserable conditions of recovery. This decision, in the opinion of every impartial critic, concludes the controversy. The sole responsibility of reopening the question rests with the German doctors. It is the multiplicity of their charges against the honor and the skill of the English specialist which compelled him to reply, and provoked him to retaliate in the same strain.

"A most important piece of evidence is furnished by Mr. Prothero on one of the crucial questions, to which we have had more than one occasion to refer, and of which we were the first to publish the details (*Journal*, May 12, 1888, p. 1029), namely, the events which occurred on April 12, 1888, when Professor von Bergmann was summoned to the Emperor on account of 'difficulties with the cannula,' to use the words of Sir Morell Mackenzie. The following is the account given by Mr. Prothero, on the highest authority:—[The scene] 'was thus described to me by an eye-witness who is not one of the principals in the struggle. A slight change in the cannula was considered necessary by the physician, and, from courtesy to the surgeon engaged in the case, Sir Morell summoned Von Bergmann. The Professor arrived in a state of extreme excitement. Striding across the room, and ignoring the English doctors, who wished to explain the object for which his presence was required, he made his way to the table on which the tubes were placed. Among them was a German tube, modified indeed after the experiences of February, but still with sharp edges and the shape of a cheese-scoop. Seizing this instrument, and placing his two thumbs on the shield, he endeavored to force it away from his body into the patient's windpipe. Unable to find the well-worn passage with the instrument, he thrust his finger into the orifice, and tried again. The blood spurted out; the Emperor was choking, and blowing the crimson bubbles into the air. The strength which the professor employed forced the tube, not into the windpipe, but into the tissues of the neck in front. At length, sinking back into a squatting posture upon his heels, he asked that Bramann should be summoned. The assistant came, and, while the professor held open the sides of the incision, slipped the cannula into its place. Upon these surgical laurels Von Bergmann practically retired. But his excited violence left a deep impression on the Emperor's mind, and, in Sir M. Mackenzie's opinion, fatally influenced the course of his malady.'"

Obituary.

HENRY B. SANDS, M.D.,

NEW YORK.

Dr. Henry B. Sands, the acknowledged leading surgeon of this city, died suddenly of heart failure, on November 19th, in the fifty-eighth year of his age. Although Dr. Sands had had some warnings of impaired health, his death was most unexpected. He had been apparently well the morning of his death, and, after attending church, had driven to the residence of Dr. A. A. Smith, with whom he started off again to see a patient in consultation. While returning home, with very little warning he fell back in his carritge seat, dead.

Dr. Sands was born in this city, September 30, 1830. His preparatory education was obtained at a high school in this city. He graduated from the College of Physicians and Surgeons in 1854, and subsequently became interne at Bellevue Hospital, and then went abroad to pursue his studies. On his return, in 1857, he was made Demonstrator of Anatomy at the College of Physicians and Surgeons, and, subsequently, Professor of Anatomy, and then of Surgery. From 1860 to 1870 he was business partner of the late Dr. Willard Parker. In 1861 he was made attending surgeon to the New York Eye Infirmary and St. Luke's Hospital. These he retained until 1863, when he became surgeon to the Bellevue and New York Hospitals. His last position was visiting surgeon at Roosevelt Hospital, from which he resigned only last spring. He was married in 1859 to Miss Curtiss, of Brooklyn. Two of his children by this marriage—Dr. Robert A. Sands and Miss Josephine Sands—survive him. His second marriage, in 1875, was to a daughter of Peter Hayden. One son by this marriage is living.

Dr. Sands was a member of the New York Academy of Medicine, the County Medical Society, the Pathological Society, the Physicians' Mutual Aid Association, the Society for the Relief of Widows and Orphans of Medical Men, and of the Medical and Surgical Society. He was also connected with the New York Philharmonic Society.

At the time of his death, Dr. Sands enjoyed the largest consulting surgical practice in the city. This was due, not only to his high reputation with his professional brethren as a surgical adviser and operator, but largely, also, to the estimate which the general public placed upon the value of his professional services. By an extensive hospital experience of over a quarter of a century, he won for himself a standing, as an authority on all branches of surgery, which was not approached by any of his associates. Although not an old man, he was naturally looked to as the fatherly adviser of everyone who aimed to make his mark in surgery. As an operator, he was cool, precise, determined, and judicious in his methods; and as a teacher, was interesting, impressive, practical, and instructive. Affable in manner, and firm in his own convictions, he always encouraged free discussion of the points in debate, and was always courteously respectful of the opinions of others. Consequently, at society meetings, when surgical matters were brought up, and he was present, the discussion was never considered complete until Sands had also given his opinion. His contributions to surgical literature, although not voluminous, were of great value as detailing the results of a remarkably extensive experience, backed by ripe and sound judgment.

Society Reports.

AMERICAN ACADEMY OF MEDICINE.

Twelfth Annual Meeting.

Tuesday, November 13, 1888—Morning Session.

The Academy met in the Governors' Rooms of the New York Hospital, at 10.30 A.M. The President, Dr. Frederick Henry Gerrish, of Portland, Me., in the chair.

The minutes of the last annual meeting were read and approved. The deaths of the following members were reported: Dr. C. R. Agnew, of New York; Dr. M. H. Bosland, of Pittsburg; Dr. Howard Pinkney, of New York; Dr. Theodore T. Wing, of Susquehanna, Pa.; Dr. E. S. Dunster, of Ann Arbor, Mich.; and Dr. Stephen B. Kieffer, of Carlisle.

Dr. Leartus Connor, of Detroit, Mich., read the

REPORT OF STANDING COMMITTEE ON THE REQUIREMENTS FOR PRELIMINARY EDUCATION IN THE VARIOUS MEDICAL COLLEGES IN THE UNITED STATES AND CANADA.

There are in the United States 116 medical schools. According to their announcements, 89 exact certain educational requirements, but 19 of these require no more than they can help.

It is futile to endeavor to directly influence medical colleges to make these requirements. It can only be obtained by awakening in the mind of the profession and people a sentiment that a definite preliminary education is necessary to the medical student.

Dr. A. L. Gihon, United States Navy, offered the following resolution, which was adopted:

Resolved, That the American Academy of Medicine expresses its high approval of the aid afforded to the cause of higher medical education by the College of Physicians and Surgeons of New York, in its recent requirements for matriculation, which it commends to the profession as worthy of adoption.

The paper was discussed by Drs. Canfield, of Baltimore; Sell, of New York; Stoddard, of Rochester, and McIntire, of Philadelphia.

Dr. J. C. Wilson, of Philadelphia, read a paper on

THE CAUSES AND PREVENTION OF THE OPIUM HABIT AND KINDRED AFFECTIONS.

The causes may be grouped under three heads: First, example, as is shown in the case of those who become opium-eaters through the example of friends. Second, suggestion, as is shown in those who fall into this habit through the reading of literature concerning it, or from familiarity with the drugs, as in the case of doctors, druggists, nurses, and students of medicine. Third, medical prescriptions. It is an unfortunate fact that the greater number of the victims of habitual vicious narcotism become so through the prolonged abuse of narcotics originally prescribed for the relief of pain.

Among the measures suggested for the prevention of the formation of such habits, were, first, the dissemination of a wholesome knowledge of the methods by which the opium habit and kindred affections are induced; of the serious character of these affections, and of the danger attendant upon an ignorant and careless employment of narcotics. Second, a reasonable and temperate presentation of the facts in the popular works upon hygiene. Third, the exercise of every possible precaution on the part of physicians in prescribing narcotics. It is good practice to keep the patient in ignorance of the character of the anodyne used and of the dose. Physicians should personally control, as far as possible, the use of such drugs, and see that they are taken infrequently and in the minimum amounts capable of producing the desired effect; the occasional alternation of anodyne medicaments is desirable. Prescriptions for drugs of this kind should not be renewed by druggists without the written order of the physician. Finally, a merely palliative treatment should not be allowed to assume too great importance in the management of curable painful affections.

Under no circumstance, except in the final stages of hopelessly incurable painful affections, should the hypodermic syringe be placed in the hands of the patient.

Uniform and efficient laws to regulate the sale of narcotic drugs are desirable. Existing laws, relating to this subject, are a dead letter; they are neither adequate to control the evil nor is their enforcement practicable.

Dr. Theophilus Parvin, of Philadelphia, read a paper on

THE IMPORTANCE OF PRACTICAL OBSTETRICS IN THE COURSE OF INSTRUCTION GIVEN BY MEDICAL SCHOOLS.

A recent visit to Munich, where he spent some time observing the method of teaching obstetrics in the University of Bavaria, pursued by Professor Winckel, made him conscious of the great deficiencies of the American plan of obstetric instruction. The science of obstetrics is admirably taught in our medical schools, but the vast majority of American medical students graduate without having witnessed a case of labor. There is also reason to believe that the mortality of private practice is greater than that of hospital practice. While attendance on poor women at their homes is better than no practice at all, yet the student will derive more benefit from the study of cases collected in a maternity hospital, where many cases can be studied under the instruction of a competent teacher. There should, therefore, be a maternity belonging to every medical school in which obstetrics is taught. Through the efforts of the author, the Trustees of the Jefferson Medical College authorized the establishment of a maternity department in connection with the hospital; 34 women have been confined without a death. The room being insufficient, an out-door department was established. Here there have been 151 applicants; 106 have been confined, with but one death. This occurred two weeks after labor. The cause of death was not positively ascertained.

The author then described the methods employed at the Bavarian University, basing his remarks on a report furnished by Dr. J. Clifton Edgar.

In concluding, Dr. Parvin said: "Why would it not be wise for this Academy, which should be a light and a guide to the American profession, leading it to higher, and giving it larger, views on those duties and responsibilities, with hearty unanimity declare that practical obstetrics should be made a part of the regular course in every medical college? With the seal of your approval, those who are laboring to this end will be given strength and hope. May the time soon come when every medical school upon the continent which does not take steps to make this necessary reform, shall perish under the common and condign popular and professional damnation."

Afternoon Session.

The first business was the delivery of the Presidential Address by Dr. F. H. Gerrish, of Portland, Me.

Reference was first made to the necessity for something more than a mere grammar school education as a preparation for the study of medicine. The course of a student without proper preliminary education was traced at length. Until recently, any male of the human species who would pay the necessary fees, found no difficulty in entering. A few years ago several medical schools established a preliminary examination. This was attributed by the speaker largely to the action of the Illinois State Board of Health, to the effect that if the schools wished their diplomas to be recognized in that State, they must have a preliminary examination. He thought that the labors of the Academy should be to elevate the standard of medical education, rather than the investigation of scientific problems.

The next portion of the paper was devoted to a consideration of the methods by which the membership of the Academy could be increased.

The President then referred to certain amendments which had been proposed at previous meetings. One of the amendments considered related to Art. VIII., Sec. 1, which now reads: "The Fellows of the Academy, in their relations with each other and with their fellow-men, agree to be governed by the principles embodied in the present code of ethics of the American Medical Association, and by the constitution and by-laws of the Academy." The amendment suggested is: "The Fellows of the Academy will be governed by those principles which actuate educated, cultured, and honorable men in every profession and by the constitution and by-laws of the Academy." The speaker favored the adoption of the amendment.

Never before had it been appropriate to address the Academy as "Ladies and Gentlemen," but to-day it was his privilege to use this significant expression. It is not creditable to our country, or in keeping with the liberality which theoretically characterizes our institutions, that a discrimination should have so long been made against women in scientific associations.

Dr. R. Lowry Sibbel, of Carlisle, delivered

A FEW WORDS CONCERNING OUR ACADEMY.

The Academy was organized in 1876, at a time when the standard of medical education was at its lowest point. The Academy has strongly insisted upon the necessity of preliminary education. At the time of the organization of the Academy there were in no State laws relating to the practice of medicine that could be enforced. Most of the States now have laws which can be carried out, and many have State Boards of Examiners. Graded courses have been adopted in the best medical schools, with preliminary examination and frequent written examinations. The "diploma mills" no longer exist.

The Academy is the only society in which an academic qualification is required. The Academy had set a high standard for admission, but he believed that the doors should not be closed against those eminent practitioners who, although they did not possess the degree of A.B., had pursued protracted courses of preliminary study in literary schools.

Dr. George Jackson Fisher, of Sing Sing, N. Y., read a paper on

THE FAMOUS HISTORIC MASTERS OF THE HEALING ART WERE MEN OF CLASSICAL EDUCATION.

The author showed that Hippocrates had bestowed upon the world a symmetrical and systematic body of medical and surgical science, founded on the tradition and records of his predecessors; that the ancient Greek Asclepions were hospitals and clinical schools, presided over by priest-physicians, of whom Hippocrates was one of the most distinguished. Reference was made to the extent and influence of the Alexandrian school of philosophy in the days of Aristotle, Herophilus, and Erasistratus. From this the author came to speak of the first century of the Christian era, and gave an account of Celsus, the Roman. Pliny, Dioscorides, and spoke of the advanced condition of the healing art in that early age. The second century gave birth to Claudius Galen, of Asia Minor, who flourished chiefly in Rome. It was shown that Galen, as well as all the previous historic masters of the healing art to which allusion had been made, was a man of genius and profound learning. Having shown that Galenic medicine was broader and deeper in its scope and influence than that of antecedent ages, the essayist proceeded to tell the interesting story of the manner in which medical science was preserved from extinction during the dark ages. He traced the modes by which it was conveyed into Persia, translated into Syriac and Arabic, annotated, tinctured with Oriental ideas, and returned to Europe in the "studies of the Saracens."

The invention of printing and its potency in distributing the existing science of that day was next considered. Then followed the period of the new birth, the revival of letters, the discoveries in anatomy, physiology, and surgery. Vesalius and his great work, the labors of Fabricius and Harvey, and of their contemporaries were briefly mentioned. All these teachers were also shown to have been men of classical education. Dr. Jenner, and the inestimable blessings which he conferred upon mankind, were next considered. The invention of the stethoscope by Laënnec in 1815; the contributions of Sir James Y. Simpson to obstetrics and gynecology; and the still more brilliant services of Dr. J. Marion Sims, were strongly and justly held up for our admiration. Dr. Ephraim M. Fowell, the "Father of Ovariotomy," his followers, and their triumphs were duly remembered. All of these great leaders in medicine and surgery were shown to be men of classical education.

The speaker next referred to the extent of medical literature, to the necessity of being trained to study and research as a preliminary to entrance into the sacred temple of Æsculapius. He emphasized the fact that all the enduring literature of medicine, and all the substantial improvements, discoveries, and progress through all time, have emanated from learned and talented men; that scarcely anything is owed to the illiterate of our profession. The paper concluded by urging the necessity of keeping a vigilant guard at the doors of the temple of Æsculapius, and if possible to prevent any from entering who are not "duly and truly prepared," not possessed of kindness of heart, of good common sense, of fair ambition, and of sobriety, honesty, and industry.

Dr. L. Duncan Bulkley, of New York, read the last paper of the session, entitled

THE RELATIONS BETWEEN THE GENERAL PRACTITIONER AND THE CONSULTANT, OR SPECIALIST.

In a previous paper the author had shown that specialism was a necessary and healthy outgrowth of general medicine. The object of the present communication was to point out the mutual relations which should exist between the general practitioner and the consultant, or specialist.

Adjourned.

The annual banquet was held Tuesday evening.

Wednesday, November 14th—Morning Session.

Dr. Charles Carroll Lee, of New York, read a paper on

THE NECESSITY FOR POST-GRADUATION INSTRUCTION IN THE PRESENT STATE OF AMERICAN MEDICAL EDUCATION.

The first post-graduate medical school was opened in New York in 1882. There are now six in operation in different medical centres. These courses are attended by practitioners anxious to brush up on certain subjects.

It is difficult to conceive how London, Berlin, or Vienna can offer greater facilities for clinical teaching than are to-day available in this city. To the medical teacher, a frequent European visit is desirable, not only to perfect his methods of instruction, but to liberalize his mind; but the time has arrived when, if the American teacher of medicine does his whole duty, the American student should lack no practical knowledge of his profession.

Dr. Henry I. Bowditch, of Boston, read a paper entitled

TOLERANCE AND INTOLERANCE IN MEDICINE; CODES OF ETHICS; WHAT CODE SHOULD THIS ACADEMY ADOPT?

He took, first, the ground that tolerance and intolerance are, in the world at large, two great moral forces, and in the line of resultant of these two powers the world has been, and will be forever, carried forward He then referred to history to show how these forms, at times, have actually changed places and made vice appear to be virtue, etc. Hence they must be used cautiously and understandingly.

Turning to medicine, he found that intolerance has almost invariably been ready to oppose *any new* idea. Ambroise Paré, Jenner, etherization and Morton, thoracentesis by Wyman's method, are brought forward as proving the above assertion.

The fact is, however, that *toleration* has invariably at length come to the rescue, and overwhelming success has been given to any really good idea. Bacteriological researches and antiseptic surgery, with their marvellous triumphs, were referred to as having produced a degree of tolerance of new ideas unknown before, and added to the importance of specialism. He next spoke of the American Medical Association, of his great interest in it in its early days, of the gradual tyranny of its "code," even to the expulsion of the New York State Society which act produced evil results elsewhere than in New York; and, finally, he brought forward the action of the American Medical Association last year, preparatory to voting, that *no signature to codes should be required hereafter!* In connection with the New York imbroglio he referred to homœopathy and eclecticism, and expressed freely his disgust at the tyranny exhibited at the time of the expulsion of the homœopathists from the Massachusetts Medical Society. He gave his testimony, from personal knowledge of some members of these two sects, to the integrity and intelligence of some homœopathists. Finally, he cited the fact of the great success of these two sects, consequent, in part at least, on our bigotry toward them. Under this course the regular medical profession has lost caste, because of its wild attacks upon others rather than in the quiet and dignified carrying onward of its own principles. He concluded this part of his subject by advancing what some may deem the heterodox opinion, that the Academy will not recover its just position until it rescinds the vote adopting the American code of ethics. He claimed that the only true code, viz., that of the gentleman, is the golden rule of "doing unto others as you would have them do to you," a rule which, though coming down from earliest ages before Christianity, was nevertheless made sacred by Christ's words. He closed in these words:

"Gentlemen of the Academy, if all of us would make that divine rule the guide of our professional relations, tolerance and intolerance would join hands in peace; and this Academy, if it could induce all physicians to act upon it, would have accomplished one of its highest missions. God grant that this body may with each year of its growth, by the work of its individual members and by its own joint labors, tend to bring the whole profession of America up to higher grades of thought, of sentiment, and of action, so that we may at length *really become* what we have hitherto, but with unconscious falsehood, *claimed* to be—a truly *liberal* profession."

Dr. Charles McIntire, of Easton, Pa., read a paper on

WHICH IS THE LIBERAL SCHOOL?

The consideration of the following amendment to the constitution was taken up: "The Fellows of the Academy will be governed by those principles which actuate educated and honorable men in every profession, and by the constitution and by-laws of the Academy." After a prolonged discussion the amendment was laid on the table for one year.

The following resolution was presented by the council and adopted: That the Academy heartily endorses the suggestion of Dr. Parvin in his address, that practical obstetrics should be made a part of the regular course in every medical college.

Dr. Charles C. Bornbaugh, of Baltimore, read a paper on

THE MULTIPLICATION OF USELESS DRUGS.

The author referred to the continually increasing unwieldiness of the U. S. Dispensatory. The index of the fifteenth edition extends through seventy-six three-columned pages, embracing about seventeen thousand names of medicinal substances. Deducting one-third—a liberal allowance—for repetitions, there are in round numbers eleven thousand. Of this number he thought that ten thousand could be transferred to the *Index Expurgatorius* without being seriously missed. Of the 324 constituting the primary list, it has been shown that 108—one-third—are very active, 100 frequently do their work, and 16 are untrustworthy. In this connection reference was made to the very limited number of remedies deemed worthy of classification in Dr. Wood's "Therapeutics." In the sixteenth edition of the Dispensatory there is an addition of 15 pages to the index, a total of 91 pages. The editors intimate that they have discarded all the material they considered "effete," so that, although they added 600 pages, the net increase was only 167 pages. As it is time to commence the discarding process and throw overboard the rubbish, this preliminary aggressive movement on the effete is most welcome. There is an irruption of newly discovered mediums and newly devised combinations which demands arrest. The only ground for tolerance is that now and then one comes to stay with the stamp of authoritative approval.

The speaker adverted at length to the declining sovereignty of empirical conclusions, and the coming reign of pharmacology which is concerned with the action of drugs on the healthy body. The time has come for future dependence upon experiments with medicinal agents upon animals.

Dr. H. A. Johnson, of Chicago, read a paper on

THE INFLUENCE OF THE WORK OF THE ILLINOIS MEDICAL PRACTICE ACT UPON MEDICAL EDUCATION.

The Illinois State Board of Heatlh was created in 1877. One of the first acts was the passage of a resolution that the diploma of a college graduating two classes in one year would not be considered in good standing after July 1, 1878. This compelled some of the prolific schools to adopt a single graduating term. In 1880 the Board made a comprehensive study of requirements of medical schools. In 1884 the Board adopted a schedule of the minimum requirements for graduation in the State of Illinois. This has led to an increase in qualifications required by many of the schools. There are now 114 colleges which require evidence of preliminary study as a condition of admission. In 1883 there were only 45. Forty three colleges now exact a three years' course, as compared with 22 in 1883. The Board has now adopted the following resolution, defining the phrase "Medical Colleges in good standing" to mean "only those colleges which shall, after the sessions of 1890–91, require four years of professional study, including any time spent with a preceptor, and three regular courses of lectures, as conditions of graduation, and shall otherwise conform to the schedule of minimum requirements heretofore adopted by the Board."

One of the principal causes of efficiency of the Illinois Board was the fact that it was a "mixed" board. At this time the numbers who gain access to our ranks are not so numerous, but they are better qualified, and there are therefore not so many inferior men to struggle for existence. The percentage of graduates to students is lower, which means a higher standard of attainments.

"The Treatment of Uterine Disease by other than Surgical Means," by Dr. W. F. Waugh, of Philadelphia, Pa., was read by title. "The Evils of a Medical Dialect separated widely from Classical English," by Dr. Edmund Andrews, of Chicago, was also read by title.

MEMBERS ELECTED.

O. G. Given, Carlisle, Pa.; G. H. Hill, Independence, Ia.; Wm. N. Swift and Garry De N. Hough, New Bedford; H. B. Allyn, Philadelphia; Charles K. Hutter, Charleston; Charles W. Hitchcock, Kalamazoo, Mich.; Frederick A. Packard, Philadelphia, Pa.; Richard Van

Santwood, New York; Peter R. Furbeck, Goversville, N. J.; Charles A. Peabody, Worcester, Mass.; Silas D. Presbrey, Taunton, Mass.; Anthony Learned, Fall River, Mass.; Samuel L. Ziegler, Philadelphia; David C. Cocks, New York; T. M. McKeenan, Pittsburg; James S. Knox, and Addison Foster, Chicago; Henry H. Herbst, Allentown; Walter Woodman. F. E. Small, Henry H. Hunt, and Charles O. Hunt, Portland; Everett Flood, Baldwinsville, Mass.; E. V. Scribner, Worcester, Mass.; George Cary, Houlton, Me.; A. R. G. Smith, North Whitefield, Me.; William S. Searmans, New York; Albert Woodside, Tenant's Harbor, Me.; W. H. Shimond, Bangor, Me.; Alfred Hitchcock, Strong, Me.; Thomas M. Coe, Bangor, Me.; Frank W. Ring, New York; S. Q. Diven, Carlisle, Pa.; George M. Wells, Philadelphia; Edward T. Tucker, New Bedford; A. O. Williams, Ottumwa, Ia.; Matthew K. Elmer, Bridgeton N. J.; David B. Cotton, Portsmouth, O.; Edward Hitchcock, Ithaca, N. Y.; Edwin F. Wilson, Pomeroy, O.; H. D. V. Pratt, Jr., Elmira, N. Y.; George James Thomsend, South Natick, Mass.; Joshua B. Rich, Worcester; H. A. Fairbairn, Brooklyn; George G. Needham, New York; Charles L. Weed, Philadelphia; William H. Helm, Sing Sing, N. Y.; Charles A. Kirsch, New York; Frank R. Fry, St. Louis; George S. Isham, Chicago; H. A Grim, Allentown; George H. Cummings, Charles E. Webster, and Charles D. Smith, Portland, Me.; Francis E. Hitchcock, Rockland, Me.; Stanley P. Warren, Portland; Emma B. Culbertson, Boston, Mass.; William S. Dennett. New York; H. B. Hill and O. C. S. Davies, Augusta, Me.; G. L. Goodale, Cambridge, Mass.; F. C. Heath, Detroit, Mich.; John W. Eveleth, Hallowell, Me.; W. G. Reed, Sturbridge, Mass.; Edward B. Weston, Chicago; George A. Wheeler, Castine, Me.; E. H. Trowbridge, Worcester, Mass.; Charles W. Foster, Woodford, Me.; F. H. Crocker, Boothbay, Me.; Adaline S. Whitney, Boston, Mass.; W. C. Mason, Bangor, Me.; Charles Edward Grom, Calais, Me.; R. G. Stanwood, Newark, N. J.; F. T. Simpson, Hartford, Conn.; Charles O'Donovan, Baltimore; Martha M. Waldron, Hampton, Va.; W. E. Rice, Bath, Me.; Julia Tolman, Arlington, Mass.; John C. Lester, Brooklyn; A. H. Burbank, Yarmouth, Me.; Charles Fuller, Lincoln, Me.; E. A. McAllister, Gray, Me.; Thomas P. Smith, Soccaroppa, Me.; John E. Walker, Thomaston, Me.; C. A. Baker, Portland, Me.; Saul B. Thombs, Knightville, Me.; John G. Park, Worcester, Mass.; A. C. Gibson, Bangor, Me.; Anna H. Johnson, E. Orange, N. J.; George W. Hale, Nashville, Tenn.; Charles C. O'Brien, Groveton, N. H.; George A. Rex, Philadelphia; R. H. Johnson, Chestnut Hill, Pa.; Wells Van Hook, Greenville, Ind.; Charles C. Cummings, Pittsburg. Total number of new members elected, 98.

The following honorary members were elected: Dr. J. H. Rauch, Springfield, Ill.; Sir Joseph Lister, London; Sir Spencer Wells, London; J. Lucas Championière, Paris; H. D. Didama, Syracuse.

OFFICERS FOR ENSUING YEAR.

President—Dr. Leartus Connor, Detroit. *Vice-Presidents*—Drs. Peter D. Keyser, Phila.; L. Duncan Bulkley, New York; Theophilus Parvin, Phila.; George J. Fisher, Sing Sing, N. Y. *Secretary and Treasurer*—Dr. Richard J. Dunglison, Philadelphia. *Assistant Secretary*—Dr. Charles McIntire, Jr., Easton, Pa.

Place of next meeting, Chicago, Ill.

Adjourned.

ALCOHOLISM AND CRIME.—In a recent communication to the Academy of Medicine on alcoholism and criminality, M. Maramhas stated that in examining the history of three thousand criminals undergoing sentences of various lengths, he found that of the vagabonds and beggars there were 79 per cent. who were confirmed drunkards; of assassins and incendiaries from 50 to 57 per cent.; of thieves and swindlers 71 per cent., while of those convicted of violence to the person there were 88 per cent., and 79 per cent. guilty of violence to property.

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, November 15, 1888.

ABRAHAM JACOBI, M.D., PRESIDENT, IN THE CHAIR.

IT being the anniversary meeting, the regular business was suspended, and the President, in some written remarks, explained to the mixed audience present the objects of the Academy, its democratic organization, what it had done, was doing, and expected to accomplish for the benefit of the public health and the advancement of science, and then in eulogistic terms introduced the orator of the evening, Dr. D. B. St. John Roosa, who chose for his subject,

THE UNITY OF THE PROFESSION, AND THE MEANS OF PROCURING IT.

In accepting the honor conferred upon him by the Council of the Academy for the second time, of preparing and delivering the anniversary discourse, retrospections and reflections arose which were at once tinged with sadness and illumined with cheer. Fourteen years ago, when he filled the same place, there was a goodly list of names upon the rolls which had since become sadly broken. Austin Flint was President, and there were among the fellows Clark, Delafield, Hamilton, Van Buren, the two Drapers, Elsberg, Krackowizer, Post, Parker, Peaslee, Marion Sims, James R. Wood, Agnew, and others who had gone over to the majority. This array of the departed awakened the saddest of reflections, but at the same time it stirred the liveliest feelings to think that our profession had made for them an arena of intellectual and moral triumph, and that we had been at all worthy to be their associates.

Although the Academy, with such a membership, held a high position in medical circles throughout the civilized world, and was the medical association of the highest rank in our city, it then had no hall of its own, and held its meetings in the lower lecture-room of the College of Physicians and Surgeons, having just migrated from the small chapel of the University. Its library was unknown to the average member. The membership was about one hundred and sixty. During the past fourteen years we had obtained a hall in a house of our own; we had a library of no mean proportions, and a reading-room richly supplied with journals and magazines from all parts of the world; while sections representing nearly every department of our art vied with each other in attendance and interest. The membership had increased to nearly six hundred. Besides this, we had hopes of soon obtaining a hall and rooms in some degree adequate to our needs and proportionate to the high position of the Academy in the medical world.

After these introductory remarks Dr. Roosa turned to the subject of the unity of the profession. In the profession of the law the members, however they might differ in opinions, ability, or experience, had no qualifying or distinguishing prefix to indicate their mode of practice, and there was no good reason why this condition of things should not obtain in medicine, and every member of this profession be simply a physician or a surgeon. But how far were we from this ideal? In this State we had three distinct classes of physicians, besides a host of unclassified irregulars not recognized by the Legislature, but having more or less influence upon the community. A profession which held such vital relations to the welfare of the human race should not be divided into conflicting parties, for there is but one science of medicine. He thought a little reflection would convince even those who may not have given the subject any consideration, that the medical profession of this country did not, as a body, hold quite the same rank, did not have quite the same authoritative influence upon the public at large as did the church, the law, or the press. But in what might be called private, or personal, relations, no man was more potent than the physician. But this individual relation to the patient had nothing to do with the profession as a body. The day had passed when the physician should be regarded solely in this isolated relation. There was the specialist, who was conscious of having but the temporary acquaintanceship of his patient; the expert hygienist, who labored for the prevention of epidemics and their repression; and the scientist in the laboratory, working at the great problem of the cause of disease; also the chemist, the medical journalist, the teacher of anatomy and physiology, and. in fact, the many specialists; and yet all members of the medical profession quite as much as the general practitioner. During the nineteenth century the profession had been passing through a stage of disintegration, about which many had been unduly anxious. Yet it must be admitted that, just as society in the nineteenth century had not caught up with many of the changes introduced by steam and electricity, and found some of them inconveniences rather than blessings, in the same way the medical profession had not as yet adapted itself to the apparent divisions in the activity of its members; the point of complete fusion had not yet been reached. The time was not yet ripe for the complete adjustment of specialism to general medicine, but it was very fast becoming so.

But it was of a unity of a higher, or rather of a broader, character than that between specialism and general medicine that he was to speak about. It was of the condition once existing in this State, which allowed all those who in any way by their work in life, either in studying the structure of the human frame or the causation and nature of disease, were contributing to the mitigation or cure of physical suffering, to unite as members of the medical profession under the common name of physicians. In discussing the means for again securing this unity he wished only to consider the State of New York. In studying its medical history, and reasoning from it, we might find ample ground for re-establishing that unity.

At this point Dr. Roosa contrasted the social standing of the physician in America with that of those in other countries, particularly in England. Here no obstacle stood in the way of the physician securing any position which his merits justified, whereas in England, unless, under unusual circumstances, the disability was partially removed by knighthood, he did not rank as a gentleman; yet the profession there, on a scientific basis, was one of the most honored in the world. But regarding many things, the medical profession in this country had not sufficient power, as in private and public sanitary affairs, in the prevention of epidemics, the government of hospitals, etc. We were divided into so many parties, each crying its shibboleth, that the public at large had come to believe that, however skilled the doctor might be in the management of the sick, he needed a good deal of lay oversight and repression when he assisted in matters pertaining to public health or hygiene. Fortunately, however, the United States Army and Navy had been trained differently. Our lack of unity depended not upon want of social position, nor upon the estimate of us which the public had voluntarily assumed, but upon our own bickerings and quarrels. When the present century was entered upon, the medical profession in New York State was a unity. The doctor was a doctor, without any further recognition. He was a graduate of the medical schools and licentiate of the county society, and was allowed to practise after a rigid examination. The State Medical Society was a part of the legal machinery of the State, and although the science of medicine did not have the exalted position it has to-day, yet the medical law gave excellent tone to the profession. But not content with its position as recognized by the political power of the commonwealth, the medical profession undertook to repress opinion as to treatment of diseases. The heresy was not as to the ascertained facts in anatomy or physiology; it was not a question as to how the human body was constituted, but as to what drugs were to be given in cases of ascertained disease, and as to what was the principle upon which they acted. A heresy, in short, upon subjects—however it may have been fifty years ago—regarding which there was no orthodoxy to-day; and the heretics whom they tried to punish were not, like the Thomsonians, uneducated men, but trained in schools with other members of the profession. and in good standing in societies, and under the protection of the law. Let it be granted that the theories of the heretics were absurd, and their remedies useless; what, he would ask, had become of many of the theories and remedies of our ancestors? The followers of Hahnemann were driven out, they appealed to the State, the State recognized them, a new Medical Society was formed; the Thomsonians, or Eclectics, as they preferred to be called, took advantage of the amnesty then claimed for all irregulars, and the unity of the profession was broken. The standard as to what constituted a doctor in medicine fell to the requirements of the three State Medical Societies and the tone of the several colleges from which they got their recruits. The State had actually stepped in to lessen the requirements necessary to constitute a doctor. It was now easy to see that no harm would have come from little pills, or vegetable remedies, or cold water, if the absurd opinions had been treated as they are now; while the educational requirements for practice might have been rigidly maintained.

What was the remedy for the present disunited condition of the profession in this State? It was not to be found in making a common standard for the degree of doctor of medicine, but in making a common standard for the license to practise medicine. The degree should be conferred, as now, by each college according to its own ideas as to what constituted a sufficient education for that honor; but the liberty to practise medicine should not be left in the hands of bodies, however respectable and however distinguished, who were only responsible to themselves. This view had twice in succession been unanimously approved by the Medical Society of this State. The necessity for it had been plainly set forth by Dr. Loomis, its late president, and also by the able counsel for the Medical Society of the County of New York, Mr. Purrington. The colleges in this city were excellently equipped, and their faculties of the highest standing, yet no graduate could enter the army or navy, and treat sick soldiers and mariners without a further rigid examination; nor be accepted as interne to any of our city hospitals. Surely the public should demand as strict a scrutiny into the qualifications of the doctor as was required for the protection of persons in hospitals or serving in the army? Dr. Roosa did not approve of exacting a Latin and Greek collegiate course. A certain preliminary education should be demanded, but students ought not to be required to spend as many years as it took to pass through Yale or Harvard, and in the study of subjects not essential in their professional duties. The composition of the medical examining board could be such that none would be excluded from practice because of peculiar views on therapeutics.

At the conclusion of the oration the audience was invited to inspect the halls and library.

Disease in Books.—The man who is not prevented from turning book leaves with a wet finger by fastidious refinement may well pause for fear of microbes. The authorities at Dresden have been investigating the question whether circulating libraries are not mediums for the spread of infectious diseases. They rubbed the dirtiest leaves of the books, first with a dry finger and then with a wet, microscopically examining the product in each case. In the first case, scarcely any microbes were found on the finger; in the second case, plenty. Though all these appeared to be of a non-infectious character, the committee winds up with a recommendation to readers not to wet the finger in the mouth for the purpose of turning over the leaves

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE SURGICAL ASPECTS OF TYPHLITIS AND PERITYPHLITIS—THE VALUE OF EARLY SURGICAL INTERFERENCE—MEDICAL MATTERS IN PARLIAMENT—THE LUNACY COMMISSIONERS—THE VACCINATION VOTE—A CURIOUS LAW CASE—THE PREVALENCE OF DIPHTHERIA—A WANT OF ISOLATION ARRANGEMENTS—DIPHTHERIA SPREAD BY CATS—DEATH OF DR. LAVIES—THE METROPOLITAN POLICE SURGEONS' ASSOCIATION—ANOTHER MURDER AT THE EAST-END.

LONDON, November 13, 1888.

THERE was a very good audience at the Medical Society on Monday evening last to hear Dr. Bull, of New York, read his paper on "The Surgical Aspect of Typhlitis and Perityphlitis." He advocated early surgical interference. While surgeons had preached early intervention, their practice, he said, had not always been early enough to save the life of the patient. He divided the cases into three groups, viz.: (1) Those in which the abscess was opened without penetrating the peritoneum; (2) those in which the peritoneum was opened for supposed perforation; (3) those in which the abdomen was opened on the strength of threatening symptoms. The general rule of opening up purulent collections as soon as detected was one which had met with general approval. The first advance was made by cutting down for pus before fluctuation had been detected, thus preventing the possibility of an accumulation. Then came the idea that constitutional signs alone might be sufficient to show whether or no pus was present. This, however, did not help them in peritonitis from perforation. Such cases were anxious ones, and would continue to be so until they insisted upon an exploratory operation before the peritonitis became general. Among the symptoms, he especially insisted upon the importance of fever and shivering. The abdomen and rectum should be frequently examined, tenderness and the presence of an area of dulness indicating the presence of pus. The outline of the cæcum might be made out, filled with fæces, and that might exist alone or in connection with a less distinct area of induration. The abdomen might become tympanitic with debility, loss of appetite, sweating, and marked anæmia. To determine the presence of pus under these circumstances the exploring needle was the best instrument. The risk was small with proper precautions. Exploration in case of doubt was preferable to waiting for unequivocal information. The operation for perityphlitis might be laparotomy or mere incision. In washing out the cavity no solution should be used stronger than 1 in 10,000 of corrosive sublimate, or 1 in 100 of carbolic acid. He concluded by remarking that the risk of operation was less than that of waiting. Mr. Treves said that, clinically, one heard a good deal of inflammation of the peritoneal investment and cellular tissue of the cæcum, but the fact was no cellular tissue existed round the cæcum. He thought the appendix vermiformis played a prominent part in the production of typhlitis; in seventy per cent., of the cases it had been found to be the source of the mischief. Referring to extra peritoneal abscess, he said it was difficult to understand how pus originating within the cæcum could find its way outside, but, as Dr. Bull had pointed out, it was rare to find pus round the cæcum except in connection with pus inside the peritoneal cavity. He thought the early employment of the needle risky, and disapproved of ligaturing and cutting off the appendix; it was an integral part of the intestine. Alluding to the aptitude of typhlitis to recur, he said he would operate after the second attack and remove the appendix, which was the cause of the trouble. Dr. Paramore observed that he was himself operated on by Dr. Heath sixteen years ago, and a large quantity of pus and fecal matter removed; there had been no recurrence. Dr. Weir, of New York, said that, according to some statistics he had collected, seventeen per cent. of those operated on after the eighth day had died, whereas only eight per cent. had succumbed of those operated on before that date. In most cases the trouble was due to perforation of the appendix; perforation of the cæcum was rare, occurring only three times in three hundred cases. The needle was a good means of arriving at a diagnosis, provided one fell upon the pus; but the not finding pus was no proof that pus was not present. Sometimes, where general suppurative peritonitis was suspected, no tumor could be felt, and in such cases he thought it was advisable to operate. Mr. Thornton said no surgeon of the present day would hesitate to operate when pus had been recognized to be present. He had never found washing out necessary, and thought good drainage was all that was necessary. He had often seen Sir Spencer Wells ligature and cut away the appendix, and had never seen any ill effects follow. Dr. Kingston Fowler protested against the idea that the disease was one which would not get well except by surgical interference. Dr. Bull, in replying, said he had purposely dealt only with the surgical aspects of the disease. He doubted whether patients could often be persuaded to undergo any operation after an attack had subsided, as suggested by Mr. Treves. He remarked that he had himself never met with any accidents in the use of the exploring needle. He defended the plan of washing out, and said no one would hesitate to wash out fecal matter; why should they hesitate to wash out pus that smelt as bad as fæces, and was as injurious in its effects? In reply to a question from Mr. Barker, he said he made his incision from the middle of Poupart's ligament vertically upward, and even a little outward, and he much preferred this to the median incision.

During the past week several matters of medical interest have come before Parliament. On the vote for the Lunacy Commission, the work of the Commissioners was assailed with considerable acrimony. Mr. A. O'Connor said they had discharged their duties in a singularly perfunctory manner. The increase in lunacy had been principally among the poor. He should like to know whether there was not a connection between the accumulation of the poor in the borough and county asylums and the extraordinary high death-rate there discovered. He referred also to the falling ratio of cure. A radical defect of the system was that the medical superintendents were not regarded by the Government in their scientific capacity, but as so many stewards or clerks engaged in financial and other arrangements. The present number of medical officers was totally inadequate. Mr. S. Smith protested against the plan at present in force of placing idiot children in asylums with adult pauper lunatics. Dr. Tanner said he hoped the time would come when all lunatics, whether pauper or otherwise, would be taken charge of by the State. The Commissioners did not visit often enough. It was almost criminal that patients restored to health should be allowed to associate with lunatics. There were a great many insane persons in work-houses, and boards of guardians were not fitted to deal with them, nor was proper means of treatment to be found in those places. After some time had been spent in discussing the subject, the amendment to reduce the vote by five thousand pounds was withdrawn by leave. Probably the free ventilation in the House of Commons of the matter will do something toward ameliorating some of the grievances complained of.

At the same sitting of the House a discussion on vaccination took place in connection with the grants in aid of public vaccinators. Mr. Bradlaugh moved to reduce the vote by the amount of the bonuses paid to vaccination officers in England. These bonuses were not paid in Ireland and Scotland, and he contended that they had failed to accomplish their object in this country. The president of the Local Government Board (Mr. Ritchie) defended the grants. If vaccination were a good thing (and he thought it must be conceded that it was), it was right to take precautions that the vaccination should be carried out under conditions which would secure the greatest amount of safety and the greatest amount of efficiency. Only one payment was made to the vaccination officer, but a portion of that payment was contingent on the vaccination being successful. In response to a query from Mr. Picton, he said he had arranged with the Registrar-General to let the Local Government Board know of any case where death was in any way attributed to vaccination, and he would at once direct full medical inquiry into the whole circumstances of the case. In reply to a suggestion as to the use of calf-lymph, he said it would be impossible for the Government to set up all through the country establishments for that purpose, but they did all they could to provide public vaccinators with calf-lymph. The motion to reduce the vote was defeated by 154 to 45 votes, and it is gratifying to reflect that it will be impossible to start a debate on the subject in the House of Commons in the same way on any future occasion. In consequence of the passing of the Local Government bill, the grants in question will in future be made from the local rates, and there will, therefore, be no opportunity for discussing them in the House of Commons.

A somewhat curious case has just been before our law-courts, and discloses the still unsatisfactory condition of our lunacy law. A medical man sued a lunatic and his duly appointed representative for professional fees due for attendance upon the former. In the county court the representative of the lunatic set up as a defence the plea that the claim was not recoverable without an order from the Lord Chancellor obtained in compliance with Section 11 of the Lunacy Regulation Act. The county court judge concurred in this opinion and non-suited the plaintiff, who has appealed. The result is that the judges hearing his appeal have disagreed. Lord Coleridge decided against the appeal. Mr. Justice Grantham, however, was of opinion that the Act did not mean that proper expenses, properly incurred, could not be recovered except after an order by the Lord Chancellor allowing the same; but, as junior judge, he withdrew his judgment, with the result that the unfortunate plaintiff has lost his appeal and may possibly be mulcted in costs as well. There is an old saying about doctors disagreeing, but in the present case it is a doctor who has to suffer through the lawyers disagreeing.

Diphtheria is still unduly present in London and its environs. This is probably partly due to there being no proper arrangements for isolating the cases, and thus limiting its spread. Owing to a defect in the Acts of Parliament dealing with the subject, the fever hospitals of the Metropolitan Asylums Board cannot be utilized for isolating diphtheria patients. During a recent epidemic, it was observed by a medical inspector of the Local Government Board (Dr. Bruce Low) that cats suffered much from illness, the mortality being large, and it is suggested that, in some instances, diphtheria may have been spread through their agency.

One of the most popular medical men at the West-end (Dr. J. S. Lavies) has just died. He was not only liked in his profession, but possessed social and musical talents which made him a universal favorite.

The Metropolitan Police Surgeons' Association, founded only last year, has just had a highly successful annual dinner, about eighty members and guests being present.

Another woman has just been murdered in the East-end of London, under somewhat similar circumstances to the preceding murders, and as in them, the crime has been accompanied by a barbarous mutilation of the body, the extent to which the mutilation has been carried being, however, more extensive, and the details more revolting. The opinion is gaining ground that the crimes are all perpetrated by one person, and that the perpetrator is a lunatic.

ANTIPYRINE IN SEA-SICKNESS.

To the Editor of The Medical Record.

Dear Sir: In your issue of November 10th you publish an editorial on "The Uselessness of Antipyrine in Sea-sickness," which I think is a little too disparaging.

Having lately crossed the Atlantic twice, I had ample opportunity in myself and in others to test the virtues of antipyrine in sea-sickness. Both the outgoing and the return voyage began with a storm which lasted three days, and almost all the passengers, including myself, were laid up.

I took in divided doses thirty grains of antipyrine on each of these days, and although they did not enable me to go on deck while the storm was at its height, yet I was made comfortable enough in my berth to pass away the time in reading. Other passengers who took this medicine on my recommendation agreed with me that, while the remedy did not cure them of their sickness, it made it more bearable by lessening their nausea, by relieving them of their headaches, and by soothing the pains in their bowels.

But it was in the sequelæ of sea-sickness that I found the antipyrine of great value. It acted like a charm for the headache, the abdominal pain, the nausea, and other nerve-phenomena which so often linger on indefinitely after the brunt of sea-sickness is over. By five-grain doses given every two hours during one morning, I got on deck the next day two ladies, who lay on their backs for over a week, unable to keep down any nourishment whatever. One of them was a lady physician from Syracuse, N. Y., whose name I have forgotten, but who I hope will see this letter and corroborate my statements. The first dose made a new woman of her.

This success gave the antipyrine such a reputation that my stock was soon exhausted by a run upon it from those who were suffering from the after-effects of sea-sickness, all of whom were invariably relieved by it.

Yours truly,
William Goodell, M.D.

Philadelphia, November 14, 1888.

THE CURABILITY OF URETHRAL STRICTURE BY ELECTROLYSIS.

To the Editor of The Medical Record.

Dear Sir: I am sure you will allow me, as an act of justice, a short space in your esteemed journal for an explanation regarding Dr. Keyes' paper, reported in The Medical Record, September 22d, and commented upon in your editorial of November 3d. The paper referred to was read by Dr. Keyes at the annual meeting of the Genito-Urinary Surgeons in Washington, and entitled "The Curability of Urethral Stricture by Electricity: An Investigation."

Case 8 of Dr. Keyes' paper, which is commented on by your reporter as "the case treated by Dr. Newman, apparently the most conspicuous failure," has been incorrectly reported by Dr. Keyes. Against my earnest protest it was withdrawn from my treatment, when improvement had fairly progressed, and I had written, June 28th, to Dr. Keyes that "the patient is not well, nor cured." The case was sent to me under the following circumstances: Dr. Keyes asked me to treat it as a charity case for his (Dr. Keyes) benefit, and the man was escorted to my office by the doctor's assistant for treatment, and taken away again in his custody. Dr. Keyes personally never came near me. I knew nothing whatever about the patient, except what Dr. Keyes wrote me, and nothing of him in the intervals of treatment. Up to the withdrawal of the patient Dr. Keyes never intimated to what use he wished to put this case, but led me to believe that I was treating the patient for his benefit, that he might see the progress. When I heard what use was to be made of the case I personally went to Dr. Keyes and protested against his using it in so unfair a manner. Then Dr. Keyes answered that he could not very well rewrite his paper, but might state verbally my objections.

More details of explanations would be given, if space for such was allowed; but without any comments I leave it to your readers to draw their own conclusions regarding the value of this case as a test one against my method of treatment.

Now as to Case 9. This case, as related in the paper mentioned, is by no means a test one. The patient, as Dr. Keyes himself acknowledges, had been made worse under the electric treatment of a physician in Brooklyn. The man then came to me for treatment, and after a few times seeing and improving him, I refused for good reasons further treatment. He then asked me to name him a reputable genito-urinary surgeon, and I sent him to Dr. Keyes.

This case also the doctor uses against me, and as a proof against the success of electrolysis.

That Dr. Keyes, with his assistant, have not cured their patients with electrolysis, only proves that they have failed, but not that electrolysis is a failure, and by no argument of sophistry or stretch of the imagination do their failures undo the great number of successes obtained by other men. If I had been the only man who succeeded with electrolysis some might doubt such reports; but the success is well established throughout the world, even to Australia, by hundreds, well, thousands of cases, and so reported by most trustworthy medical observers. I will mention only a few whose reports of successes cannot be contradicted, as, W. F. Hutchinson, T. F. Frank, David Prince, Jacob Butler, J. H. Glass, T. H. Burchard, W. T. Belfield, George E. Pitzer, C. A. Bryce, G. W. Overall, A. T. Douglass, D. O. Farrand, A. S. Wolff, J. B. Green, G. C. H. Meier, R. J. Nunn, T. F. Sanders, J. Craft, W. C. Wile, and many others in the United States. In Great Britain we find pre-eminent W. E. Steavenson, W. Bruce Clark, Edwin Morton, T. J. Hayes, F. Swinford Edwards, etc. Next comes Canada with C. R. Dickson, J. J. Cassidy, E. King, A. Lapthorn Smith, etc. Here is success of electrolysis in urethral stricture by an array of talent, against the failure of Dr. Keyes and a few inexperienced operators. The readers may make their own comments.

ROBERT NEWMAN, M.D.

63 WEST THIRTY-SIXTH STREET, NEW YORK.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department. United States Army, from November 11, 1888, *to November* 17, 1888.

BAILY, ELISHA I., Colonel and Surgeon. By direction of the Secretary of War his retirement from active service this date, by operation of law, under the provisions of the act of Congress approved June 30, 1882, is announced. Colonel Baily will repair to his home. Par. 1, S. O. 266, A. G. O., Washington, November 14, 1888.

NORRIS, BASIL, Lieutenant and Surgeon, and TILTON, HENRY R., Major and Surgeon. By direction of the President detailed as members of the Army Retiring Board appointed to meet at San Francisco, Cal., by War Department order dated October 27, 1888, published in Special Orders, No. 253, October 30, 1888, from Headquarters of the Army, vice Colonel Elisha I. Baily, Surgeon, and Captain John J. Cochran, Assistant Surgeon, hereby relieved. Par. 13, S. O. 261, A. G. O., Washington, November 8, 1888.

MCCLELLAN, ELY, Major and Surgeon. Relieved from duty at Jefferson Barracks, Mo., and to report for duty at Chicago, Ill., as attending surgeon and examiner of recruits. Par. 13, S. O. 261, A. G. O., Washington, November 8, 1888.

BARTHOLF, JOHN H., Major and Surgeon. Relieved from further duty in the Department of Texas, and to report to the commanding officer at Plattsburgh Barracks, N. Y. Par. 15, S. O. 261, A. G. O., Washington, November 8, 1888.

WATERS, WILLIAM E., Surgeon, Vancouver Barracks. Granted leave of absence for one month, to take effect on or about the 1st proximo, with permission to apply for an extension of one month. Par. 1, S. O. 129, Headquarters of Department of the Columbia, November 9, 1888.

ARTHUR, W. H., Assistant Surgeon. Upon being relieved by Acting Assistant Surgeon J. L. Ord, will proceed to comply with par. 21, S. O., No. 250 c. s., Headquarters of the Army. Par. 5, S. O. 123, Headquarters of Department of Arizona, Los Angeles, Cal., November 5, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 17, 1888.

SWAN, ROBERT, Past Assistant Surgeon, ordered before Retiring Board on the 19th inst.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 17, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	22	10
Scarlet fever	130	27
Cerebro-spinal meningitis	1	2
Measles	164	12
Diphtheria	84	23
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

REGISTRATION OF MARRIAGES AND BIRTHS.—Office of the Board of Health of the Health Department, 301 Mott Street, New York City. *To whom it may concern:* At a meeting of the Board of Health of the Health Department of the city of New York, held on October 18, 1888, at said office, the following resolution was adopted:

Resolved, That the attention of "clergymen, magistrates, and other persons who perform the marriage ceremony in the City of New York," and also of physicians and midwives who attend on births in the city of New York, is respectfully called to the following sections of the laws relating to the Health Department of the city of New York.

New York City Consolidation Act of 1882.

SEC. 602. It shall be the duty of the clergymen, magistrates, and other persons who perform the marriage ceremony in the city of New York, to keep a registry of the marriages celebrated by them, which shall contain, as near as the same can be ascertained, the name and surname of the parties married; the residence, age, and condition of each; whether single or widowed.

SEC. 603. It shall be the duty of the parents of any child born in said city (and if there be no parent alive that has made such report, then of the next of kin of such child born), and of every person present at such birth, within five days after such birth, to report to said Board in writing, so far as known, the date, ward, and street number of said birth, and the sex and color of such child born, and the names of the parents. It shall also be the duty of physicians and professional midwives to keep a registry of the several births in which they have assisted professionally, which shall contain, as near as the same can be ascertained, the time of such birth, name, sex, and color of the child, the names and residences of the parents, and to report the same on or before the first Monday of each and every month, to the Board of Health.

SEC. 605. For every omission of any person to make and keep the registry of marriages and births required by the preceding sections, and for every omission to report a written copy of the same to said Board within ten days after any birth or marriage provided to be registered; and for every omission by any person to make the report of any death or birth, with the particulars as herein required, any person guilty of such omission shall be liable to pay a fine of ten dollars, which may be sued for and recovered in the name of such department for the benefit of said department. But no person shall be liable for such fine for not making the report herein required, if he or she shall prove that such report has been made to the Board by some other person before suit brought for such penalty, or that he or she was ignorant of such birth or death.

The frequent failures of the aforesaid persons to properly report marriages and births, due to ignorance of the law or to thoughtlessness, invalidates the value of such returns for statistical purposes, and not infrequently is of injury to those who are directly interested in such births and marriages. The Sanitary Code, in Sections 160, 161, and 162, prescribes the same duty, and regulates the manner and time of such reports to be made to the Sanitary Bureau of the Health Department. Violations of the Sanitary Code may be punished as misdemeanors, and in civil suits for a penalty of fifty dollars. The Commissioners of the Health Department desire to impress on all persons who are responsible for such neglect, that the public good demands a faithful and prompt compliance with the requirements of these sections, and that a failure to properly comply with these legal requirements will subject the offender to the penalty of the law. JAMES C. BAYLES, *President*; EMMONS CLARK, *Secretary*.

THE FUTILITY OF PASTEUR'S ANTIRABIC INOCULATIONS.—The Paris correspondent of *The Lancet* writes that M. Pasteur has had a run of ill-luck with his antirabic inoculations lately, as reported by the *Semaine Médicale*. On July 23d last a man, aged twenty-eight, died of rabies at the Hôtel Dieu of St. Etienne. He had been bitten by a rabid cat on June 16th, and was treated at the Pasteur Institute at Paris from June 20th to July 7th. After having completed his treatment by the antirabic inoculations the man returned to his work as a domestic at St. Etienne, where the first symptoms of rabies manifested themselves on July 18th, that is, thirty-two days after he had been bitten. On August 8th a young man, aged twenty-two, died at the Necker Hospital, at Paris, from convulsive rabies. He had been bitten by a mad dog on the 13th of July, and was treated at the Pasteur Institute from the 16th. Death from rabies took place twenty-six days after the bite. On June 20th last a child, aged eighteen months, died from rabies at Gentilly (Seine), thirty-six days after having been bitten by a rabid dog and inoculated at the Pasteur Institute. The child, who had been bitten on May 15th last, was first treated by the doctor of the place. Two days after—that is, the 17th—the inoculations were commenced and continued for twenty-four days. The first symptoms became manifest about the eighth day after the completion of the treatment by the antirabic inoculations. A child at Marseilles, aged thirty-one months, who was bitten on May 9th last by a rabid dog, and treated at the Pasteur Institute from May 14th to June 9th, died from rabies on June 23d—fourteen days after the end of the treatment. An inhabitant of Chatenay, aged forty-four, who was bitten on March 25th last by a rabid cat, and treated at the Pasteur Institute from March 26th to April 12th, died from rabies on July 30th. Madame Sarazin, of Saint-Maurice, in Switzerland, aged forty-four, who was bitten on July 1st last by a mad dog, and treated at the Pasteur Institute from the 4th of the same month, died from rabies at the Hôpital Broussais, in Paris, on August 4th. To this list may be added the name of a workman of Chatenay, called Labeaume, who died from convulsive rabies at the beginning of the month of July last at the Hospital of Versailles, but who had not undergone the treatment regularly. Bitten on May 29th, 1888, by a rabid cat, Labeaume was put under treatment on the 30th of the same month, but he left the Pasteur Institute on June 2d without signifying his intention to do so, and only returned on the 14th. At that time he experienced severe pains in the bitten arm, accompanied with headache. The inoculations were resumed and continued till June 29th.

MERCURY SUCCINIMIDE FOR SUBCUTANEOUS INJECTION.—Dr. Vollert, assistant in the Strasburg Syphilitic and Dermatological Clinic, writes in the *Therapeutische Monatschrift* on the employment of mercury succinimide for hypodermic injection. This compound was discovered by Dessaignes in 1852, and has recently been brought into the market at a price equivalent to about two shillings an ounce. It occurs as a white shining powder, freely soluble in water, the solution being quite clear and without any tendency to become cloudy or to form a deposit, even on long standing. It does not precipitate albumen, or the fluids of pleuritic effusion or of hydrocele. Mercury succinimide appears to have several advantages over mercury glycocoll, its solution being much more stable, and the injection being less painful and causing a smaller amount of infiltration at the seat of puncture, besides which its cost is decidedly less. When properly applied, the injection rarely, if ever, sets up suppuration. According to Professor Wolff, the best way of operating is to run the needle into the middle of the subcutaneous fat of the buttock, not perpendicularly to the surface, but parallel to it, then to inject the liquid very slowly, gently stroking the swelling formed so as to distribute and disperse the liquid over a somewhat extensive area. The daily injections are made alternately into the right and left buttocks. The strength of the solution recommended by the author is two per cent., corresponding to about one per cent. of mercury, so that each Pravaz syringeful contains one sixth of a grain of mercury. The average number of injections given to each patient is about nineteen; in severe cases, however, thirty to thirty-five injections are required. Dr. Vollert has not as yet been able to make any observations on the excretion of mercury by the organism after the treatment; but, speaking from the point of view of clinical experience, after having given five hundred and twenty-three injections to twenty-eight patients, he considers mercury succinimide bids fair to prove a very valuable drug for subcutaneous injection in cases of syphilitic disease.

A TRUSS FOR MOVABLE KIDNEY.—Dr. Niehans, of Berne, has recently devised a special truss for the palliative treatment of movable kidney. He observes that Lindner, who has recently written on the affection in question, strongly recommends treatment by bandaging, since it palliates the severe pain which so often accompanies the displacement of the kidney. Extirpation of the kidney is a perilous proceeding, not only on account of the risk of the operation itself, but also because the surgeon cannot always feel certain that the opposite kidney is in working order. We may note that Landau, in his standard work, translated for the New Sydenham Society by Dr. Champneys, in 1884, strongly discountenances the operation, and shows that not only is the fellow-kidney occasionally diseased, but that Beumer has collected, out of a long series of cases of movable kidney, no fewer than forty-eight where only one kidney was found. Nor, Landau warns us, must we assume that one healthy kidney can always satisfactorily discharge the renal functions. Dr. Niehans does not think that the published results of nephrorrhaphy, or stitching the kidney, on Hahn's principle, are encouraging. Pads, such as those advocated by Guéneau de Mussy and Lindner, are hot, uncomfortable, and readily displaced; and Dr. Niehans does not notice Landau's "artificial abdominal wall," simply stays lengthened as far as the pubes and Poupart's ligament. He had under his care, in August, 1887, a woman, aged twenty-three, who suffered from pallor, dyspepsia, constipation, nausea, and other symptoms, as well as the usual pain caused by movable kidney. That condition evidently existed in her case, and she wished the offending organ to be extirpated. Dr. Niehans, however, contrived an apparatus which afforded her great relief. On the principle that the basis of support should be at the pelvis, he made an ordinary double inguinal truss. To this was fitted a steel spring, which ran vertically upward for a few inches, and then bent inward, fitting by a ball-and-socket joint into the back of a concave steel pad, oval, with its long axis horizontal. The spring was contrived so that it could be fixed on the truss in such a position as to allow the pad to lie over the right place on the abdomen. The pad, well lined with soft material, was held in place by an elastic waistband, which buttoned on to its right and left borders. This band was made light, and not too strongly elastic, lest it should pull up the truss. The pad was thus placed at the proper level, the spring next made fast to the truss, and then the kidney was pressed backward, and the waistband fastened. the patient, in the meanwhile, lying on her back. The apparatus was taken off at night. The patient was delighted with the result, all unpleasant symptoms disappeared. and she was recently in excellent health, able to do her housework. Whenever she omits to replace the truss in a morning before beginning to dress, she feels the old local pain, which lasts for about a quarter of an hour, but steadily disappears after the apparatus is adjusted.—*The British Medical Journal.*

Success in Practice in the Last Century.—Sir Walter Scott, in his essay on Dr. Smollett, the novelist, gives an idea of what was thought necessary to success in practice in the eighteenth century. Smollett "was not successful as a physician, probably because his independent and haughty spirit neglected the by-paths which lead to fame in that profession. One account says that he failed to render himself agreeable to his female patients, not from any want of address or figure, for both were remarkably pleasing, but more probably by a hasty impatience of listening to petty complaints and a want of sympathy with the lamentations of those who labored under no real indisposition. It is remarkable that. although very many, perhaps the greatest number, of successful medical men, have assumed a despotic authority over their patients after their character was established, few or none have risen to prominence in practice who used the same want of ceremony at the commencement of their career. Perhaps, however, Dr. Smollett was too soon discouraged and abandoned prematurely a profession in which success is proverbially slow."

A Peculiar Case of Rumination.—Dr. Alt has described a case of this rare affection. The patient was twenty-four years of age, and had suffered from merycismus for fourteen years. All food and drink in a few minutes or hours, sometimes even after several days, would be regurgitated into the mouth, without having undergone digestion. About fifteen seconds before the food was returned the patient knew what would happen, from a peculiar local sensation referred to the stomach. All the patient's organs were found normal, except his stomach. This was moderately dilated.

Dry Mouth.—At a recent meeting of the Clinical Society, London, among other papers read was one by Mr. Hutchinson on "Dry Mouth," or "Persisting Aptyalism," as he proposed to term it. In the paper a brief account was given of the five cases already on record, and another one was described, which had recently come under the author's observation. The patient was a widow of fifty, and, with the exception of her having gone through a great deal of trouble, there was no ascertainable cause for the condition. In the course of a few months the tongue, inner surface of the cheeks, lips, and palate became absolutely dry. The dryness had persisted for about four years. It was such that the patient had difficulty in talking so as to be understood. The pharynx was also dry, but there was no defect of nasal secretion. Neither was there any dryness of the conjunctivæ, and the tears flowed freely. Perspiration was also free, and any slight emotional excitement caused the face and forehead to perspire freely. Mr. Hutchinson remarked that in all the recorded cases the patients were women past middle age, and, in all, the condition, having once begun, proved persistent. In none had it been the precursor of any other disturbance of the nervous system. The President (Dr. Broadbent) said he had seen a case which had been somewhat relieved by iodide of potassium. Mr. Butlin related two cases. Mercury, jaborandi, and iodides gave no good results, but pilocarpine, in doses of one-twelfth of a grain, was of some benefit. Dr. Crocker narrated two cases. In one of these some relief had been afforded by keeping the lips anointed with boracic-acid ointment, and applying a lotion of chromic acid (gr. v. ad ℥ j.) to the inside of the mouth.

Dr. Hubbard's Article.—In Dr. Hubbard's article, in the issue of November 10th, the name of Dr. Samuel Ketch appears as Dr. Ketel; and "clinical experience," as *chemical* experience.

A New Use for Ether during Anæsthesia.—Dr. H. A. Hare writes to the *University Medical Magazine* that if, during anæsthesia, respiration stops, he has found that in a large number of instances, both in man and in the lower animals, the free use of ether poured upon the belly causes so great a shock, by the cold produced by its evaporation, as to cause a very deep inspiration, which is often followed by the normal respiratory movements.

One-Child Sterility.—Out of 1,081 gynecological cases, Dr. Kilenwachter, in the London *Medical Record*, noted 90 where the parents had borne one child at a more or less distant period, and had remained sterile since, although still cohabiting with their husbands. In 21 of the cases the single pregnancy had ended before term. He divided the causes of this kind of barrenness into 10 groups: 1. Sequelæ of inflammatory processes beginning during the puerperium. 2. Catarrhal endometritis. 3. Sequelæ of inflammatory processes traced to a non-puerperal origin. 4. Displacements of the uterus. 5. New growths in the uterus. 6. Constitutional sources of sterility established after the first pregnancy. 7. Impaired potency of the husband. 8. Excessive involution or atrophy of the uterus. 9. New growths in the ovary. 10. Uncertain or unknown causes. These groups are arranged in the order of frequency. Forty-three were traced to uterine and extra-uterine pelvic inflammations, that is, to the first three groups; 19 to displacements and tumors.

Treatment of Acute Cystitis.—As the urine is often highly acid in the early stage, the alkalies would be indicated; and in the later stages benzoic acid to counteract alkalinity. Various specifics have been praised—notably buchu, hyoscyamus, uva ursi, lupulin, cubebs, copaiba, and belladonna. Gross thinks copaiba in small and often-repeated doses one of the best, if not the best remedy; and, as he thinks that a combination of remedies in this particular disease better than any one individually. he combines the copaiba with, I think, uva ursi and hyoscyamus. I found in one case the capsules of copaiba, cubebs, and santal-wood apparently act well. I believe this fondness for copaiba did not originate with Gross, for Sir Astley Cooper used it extensively for the same disease.—*Canada Lancet.*

THE INJURIES OF FOOT-BALL PLAYERS.

By A. H. P. LEUF, M.D.,

DIRECTOR OF PHYSICAL EDUCATION AT THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

A NOTICE in THE MEDICAL RECORD of November 3d, of this year, calls attention to Dr. George Werry's paper in *The Lancet*, and refers to an injury to the front or outer side of the thigh that is known as "the poop." THE RECORD says:

"The description of the injury given by Dr. Werry is this:

"During the game a player receives a blow on the front and outside of the thigh; there is at once a feeling of utter helplessness, but he may recover so far as to be able to continue the play after a short rest, and feel little of it next day, except that he cannot run. The patient comes to consult the physician the day after the injury, with little pain. He limps in walking. On examination there may be effusion into the knee-joint, a soft and somewhat tender area over the quadriceps extensor femoris, and the patient cannot lift the limb when it is kept extended. Ecchymosis is not common. The amount of knee-joint effusion depends on the position of the injury with regard to the bursa behind the quadriceps tendon, and whether the man has tried to continue his sport, or walked much after the accident. The blow may be in the middle of the thigh, and cause an effusion into the joint; the patient may have forgotten the 'poop,' and come to complain of the swollen knee. The recovery of the damaged muscle is generally complete. It seems probable, therefore, that in the 'poop' the muscle is more bruised than broken."

My object in writing this note is to call attention to the fact that these injuries are very common with us in our games of foot-ball, and that they are not limited to this game, for they also occur in base-ball, though not as frequently.

Etiology.—These injuries are almost invariably due to severe direct violence, and may affect muscles, bones, periosteum, ligaments, and aponeuroses. Some are due to over-action and occur spontaneously, that is, without direct external injury.

Pathology.—The muscles are affected most commonly, and after these follow, in the sequence of their frequency of being injured, tendons, aponeuroses, ligaments, periosteum, and bone. With the exception of the muscles, these structures enter upon a condition of subacute inflammation, and rarely get well within many months, or several years, unless properly treated. Some of these cases even carry with them through life some permanent weakness, or even visible lameness, due to injuries sustained in playing foot-ball. The myositis is often quite acute, and hence painful. It is not uncommon in muscle or aponeurosis injuries to find an unmistakable inflammation of the adjacent connective tissue. If these cases are not properly handled, there results more or less atrophy of the affected muscle, and a contraction of the previously inflamed connective tissue. That this is plainly so is evidenced as follows: The injured muscle is very tender at the site of injury. There is a diminishing area of tenderness around this focal point, always extending further in the direction of the affected muscle than across its longitudinal axis. Contraction of the muscles invariably causes pain at the seat of injury or tenderness. If now an adjacent muscle, showing no tenderness, be contracted independently of the other, there will result a deep, tearing sensation that alarms the patient. From this I feel safe in concluding that there is an inflammation of the connective tissue between the contracted and injured muscle. I believe that much of the permanent stiffness in many cases is due to the adhesion of muscles to their enveloping sheaths. Tendons seem also occasionally limited in their freedom because of adhesions between them and their surroundings. Much lameness is due to chronic localized osteitis, or periosteitis, at the attachment of ligaments that have been severely strained. At other times chronic bone trouble remains at places that have been very forcibly struck in a game, say with the heel of an adversary's shoe. Joints and tendon-sheaths also very often become filled with fluid. Pathologically, these foot-ball players' injuries do not seem to me to be at all different from all low-grade inflammatory conditions of the same structures; but they are peculiar in that they are almost uniformly neglected through carelessness, over-confidence, or because of the ignorant assumption that if they do not get well of their own accord, they also cannot get well under treatment. I may also say that many boys and young men purposely hide from their parents the seriousness of an injury, because it is feared that a physician's bill of attendance will cause the parental veto of all future foot-ball aspirations. So it is readily seen that neglect makes these injuries more intractable when sustained on the field than when they are the result of accident in "ordinary every-day life." From this it naturally follows that most foot-ball injuries that come under the general practitioner's care are somewhat old and chronic, and therefore intractable. Such injuries may be divided into acute and chronic varieties, and the acute may be subdivided into those that are moderate and those that are severe. Each kind has its own symptoms and requires distinct treatment.

Symptomatology.—Almost in all of these cases that are the result of direct violence there is for a time the feeling of utter helplessness of which Dr. Werry speaks. But this symptom is not confined to foot-ball casualties, as it is well known that being hit with a swiftly pitched base-ball produces the same effect, as also a localized blow resulting from a collision in base-running. These hard, sudden blows cause a paralysis of a reflex or functional character. It is often necessary for the player to leave the field to rest, be "rubbed down," and to recover lost confidence. If not too badly hurt, he will limp back to his position and continue play. On the other hand, the injury is often so severe that he cannot play for a few days, or even weeks. If it is not great, the sufferer feels little or no pain next day, but he experiences an unusual stiffness under the skin at the site of the injury. If it happens to be at the usual place in the upper half of the front of the thigh, he will find, while running and in the act of drawing the thigh forward for another step, that it appears to be held by a band from going back as far as usual. It is this restricting band-like sensation that is meant by stiffness, and which repeated careful examinations have convinced me to be due to connective tissue and muscle infiltration of plasma. The parts are invariably swollen. The tenderness diminishes in proportion to the depth of the injury and the natural softness of the tissues. At first the pain is usually very severe for a short time, after which it is vague. The vagueness and dulness of the pain I attribute to general bruising of the nerve-fibres connected with the affected area. After a period, varying from one to four or five days, well-marked inflammatory conditions supervene, leading to increased tenderness, more or less continuous pain, additional tumefaction, and decided stiffness in walking. After two or three weeks those symptoms subside, and the patient has little or no discomfort, except during a rapid walk or while running. Ordinary pressure produces very little or no pain; but deep, firm, digital pressure at once causes decided wincing, thus making it readily possible to locate and circumscribe the disease that is in progress. Once arrived at this stage there is usually a standstill, the patient gets neither worse nor better, unless properly treated. He will rejoice in being sound and well again after several months or a year, provided that he does not exert himself very much; but as soon as he attempts to accomplish his former feats of running, dodging, and jumping, his disability returns, and if he perseveres in his efforts for a few days, the previously injured part is as bad as ever.

When aponeuroses are affected, all the symptoms are less decided, the pain is more indistinct, and the progress of the case slower.

Osseous, ligamentous, and periosteal injuries have one peculiarity that is very marked. The symptoms are those which generally accompany injuries and subsequent sub-inflammatory disease of the structures; but the patient finds that though he has no pain, and but slight and irregular tenderness, his joint, while he is walking or running, suddenly gives way under him so as to almost let him fall. This *treachery* of the joint immediately adjacent to the affected tissues is a constant, marked, and characteristic symptom. It should not be forgotten. Hydrops articuli is very common, and due more to wrenches, I believe, than to direct blows upon a joint Dropsy develops quickly, as a rule, sometimes becoming very decided within a few hours. Tendons occasionally slip out of their grooves, and either tear their sheaths or pull them partly out of their beds. The signs of this consist in well marked local tenderness, swelling, and painful and impaired motion, with resulting lameness. Without treatment these cases cause lameness for many months, and even for years.

Treatment.—In all acute cases I invariably make use of a compression support, and prescribe rest. My usual method in the most severe cases is to apply a suitable bandage, and sometimes, either because of a natural hollowness or much tenderness, I place over the seat of injury a soft cotton pad. Pressure and rest are continued for several days until moderate motion of the limb causes but a slight and indefinite feeling of pain, accompanied by a sensation of stiffness. If the pain is so severe at first as to cause much loss of sleep, I give just enough opium to cause relief, and have cloths wrung out of hot water applied locally at frequent intervals. During this period the patient keeps his room. After a few days, when the very marked symptoms have abated, the patient feels much as though he had just received a fresh injury of average severity, and such is practically his condition. The treatment is the same in both instances. It consists of regular moderate exercise despite some pain and considerable stiffness. The injured part must always be kept warm with scrupulous care. Morning and night there should be gentle kneading, and vibratory massage of the affected parts and surrounding area. At the end of another week or ten days recovery is either complete or the injury begins to get chronic. In this latter stage no little care is required to watch daily changes, for the symptoms are ever changing, and the spots of tenderness flitting about from place to place. At this stage almost any amount of exercise is admissible, provided that the part is not struck another blow, or (in the case of a joint, ligament, or tendon) does not receive another wrench. The main therapeutic reliance now is galvanism. This must be applied daily, in moderate strength, for about fifteen minutes. Interruptions of the current should cause distinct muscular contractions. The positive pole, as a rule, does best at the seat of injury. The skin should be reddened by the electrode. During a sitting the tenderness will shift under the electrode, and when followed up with the positive pole, it will shift its place again. At the beginning of the sitting the patient, as a rule, repeatedly jabs his thumb or finger firmly toward the bone in the affected area, so as to be able to identify the focus of the trouble.

I have found many times that these cases will remain permanently at a subacute stage unless they are properly handled. To me it seems that the electricity is all-important, for it appears to have a revivifying effect upon the disordered functions of the part that has been injured. I believe that it sets up a cell reaction that causes resolution.

Heat has a charming, soothing effect in all these sub-inflammatory diseases of muscle, bone, and fibrous tissue incident to injuries received during active physical exertion. The best way to apply it is by means of hot water. This may be as a hot bath (local), cloths wrung out of hot water, bottles filled with hot water and wrapped with flannels, and rubber bags filled with hot water. All are good, but I prefer the bath or rubber bags, because they are the most efficient and easily handled.

The few cases that follow may serve to illustrate the foregoing remarks.

One of the best foot-ball players now at the University, while playing last year (fall of 1887) with Princeton against Yale, was running at top speed with the ball and dodging all opponents who attempted to make a tackle, when he collided with one of the Yale team whose flexed knee struck him in the front of the thigh at the junction of the middle with the upper third. He had the symptoms of a severe injury of this kind. His gait was defective afterward, and last summer, while playing base-ball at Cape May, he found base running very difficult because of his bad thigh. At the beginning of this year's football season he came to me. He walked with a limp, had some pain at the site of the injury, which was increased upon exertion; there was tenderness on firm digital pressure, but it was not well defined; the pain was shifting; there was a sensation while running as if a band prevented the thigh from being fully extended; and he had lost his confidence in running. He was advised to keep up his foot-ball practice; he was instructed so as to treat himself to local kneading and vibratory massage; and I used galvanism daily for several weeks, at the end of which time he was well. Some weeks ago he sprained his ankle so that it swelled to at least double its former size and was discolored. I advised the hot local bath thrice daily for twenty or thirty minutes at a time, and gradually increasing exercise from the beginning. A counter-irritating liniment was also given, but mostly with an idea to the discutient effects that would result from the rubbing. He was well in about three weeks.

Another player on the team, also an ex Princetonian, had two subluxations of the left shoulder within one week. I reduced one myself on the field, and was at first certain that it was a complete subglenoid dislocation. I felt the subacromial hollow of the shoulder, noted the stiffness and abduction of the arm, the undoubted pain of the player, his relief from pain in the axilla, forearm, and hand during traction, and the audible snap when the head of the bone slipped into place. We raised him from the grass to his feet, and I put the hand of the injured arm in his breast, telling him to leave the field for the office, where a bandage would be applied. When a little way off, he tried his arm by swinging it around forward and then backward "to see if it was all right." It did not come out again, but I then concluded that the dislocation had only been partial.

The centre rush of the same team had a bad knee wrench in a game with Yale, and had to be carried off the field. Treatment soon brought him around, but he still has a little pain on the opposite side of the knee at the upper part of the femoral condyle.

One of the students at Swarthmore College last fall (1887), while pole-vaulting, either fell upon or wrenched his knee, he could not tell which. This was between five and six P. M. The next morning he had a large effusion into his knee-joint. I left him in bed and bandaged his knee for about ten days. His knee had been blistered with iodine by a well-meaning nurse, and I had given him the iodide internally. Most of the fluid was absorbed in a few days, but after that there was hardly any appreciable progress. After he left the bed and began to run around again, the effusion was absorbed in a few days.

The right fielder of a prominent National League baseball club played his position during the past season while on a trip from home, though he had so severe a dropsy of one knee that only very slight flexion was possible. The skin over it was very red, and it was painful. After six or seven weeks it troubled him no longer. That he did wisely in playing in such a condition I do not believe; but I am fully convinced, from numerous instances that have come directly under my observation, that while rest and compression of the joint are indicated until the very acute symptoms have subsided, free but not violent exercise will tend to the most rapid absorption of the fluid that may remain within the joint.

The full-back of the University foot-ball team sustained a peculiar injury. He fell upon his knee during a game, and felt the helplessness of which Dr. Werry writes, but only for a few moments. At the end of the first half I saw him in the dressing-room, and found the bursa patellæ quite distended with fluid. It was excruciatingly painful. The ground man "rubbed him down," and he continued play. He made a spontaneous recovery in about two weeks.

Another member of the same team has an effusion (well marked) at the inner side of the knee. I find it difficult to tell whether it is between the vastus internus and the joint capsule, or in the joint, but I incline to the former belief because no effusion can be felt on the outer side of the joint. He is improving rapidly under galvanism and exercise.

The same team's quarter-back in the last game against Yale, at New Haven, was piled up in a mass of players in a scramble for the ball. He did not feel injured, but when he attempted to pass the ball to one of the halfbacks, he found that his wrist was useless. He then ceased playing. I saw him on the next day, and at first suspected a fracture of the lower end of the ulna, but I was mistaken. The whole lower half of the forearm was swollen and tender. Most pain was felt along the tendon of the extensor carpi ulnaris, opposite the lower end and a half-inch of the ulna. Extension and flexion of the fingers caused pain in the forearm. I believe that his injury was due to severe squeezing of the lower half of the forearm, with perhaps a little twisting. I advised, with very satisfactory effect, elevation of the hand to reduce tension; hot applications to hasten resolution, and a counter-irritant and anodyne liniment to relieve pain, lessen and subdue inflammatory action, and for the discutient effects of rubbing.

Many more cases could be cited, but it seems to me that those mentioned will suffice to illustrate some of the remarks I made at the beginning of this note. So far I have not yet met an injury caused by foot-ball playing, that has received medical treatment, that would impair a man's future health, strength, or general usefulness, and yet the opinion is current that the game is dangerous to life and limb. Certainly it has its drawbacks, as all will admit, but, then, what has not?

I could find no player here who ever heard the term "poop" applied to a foot-ball injury. The term is probably unknown among American players, though the affection is an old and familiar acquaintance.

129 South Thirty-sixth Street.

SPLENECTOMY FOR FLOATING HYPERTROPHIED SPLEEN.[1]

By J. R. NILSEN M.D.,

PROFESSOR OF DISEASES OF WOMEN AT THE NEW YORK POST-GRADUATE SCHOOL AND HOSPITAL.

I HAVE delayed publishing these notes from my case-book to allow time to keep the patient under observation. As nothing new of interest has occurred in the case, and she has not been seen since eighteen months after the operation, I shall probably not gain anything by waiting longer.

Mrs. A. W——, aged thirty-six, married fourteen years, one child. The patient came to my clinic seeking relief from abdominal pains, which she describes as constant and general, sleeplessness, anorexia, menorrhagia, and constipation. She said nothing about "a swelling" until after it was discovered during the examination. She showed a conspicuous lack of animation. Facies long-drawn and careworn; eyes hollow; skin puffy and dark below the eyes, without œdema. Complexion unhealthy, ashen. She was poorly nourished, and anæmic. Tongue coated; breath foul. The lungs were sound; the heart irritable, with intermittent beat, and a mitral systolic murmur (anæmic?). Liver slightly enlarged, not tender. Urine normal, except for a slight cloudiness from the presence of mucus. The appetite has been poor for years. She had had frequent nausea and vomiting after eating, and occasional epistaxis. Constant pelvic pains, especially on the left side, greatly aggravated at the approach of and during menstruation, which has occurred with fair regularity. Examination per vaginam revealed enlargement of the uterus and appendages, with great tenderness of all the pelvic organs. In the left iliac fossa a tumor, clearly mapped out, although the abdomen over its site is very sensitive. It is freely movable; can be pushed upward against the diaphragm. Its shape suggests an enlarged spleen; seems about eight inches long by four or five wide. Its upper margin quite sharp.

Close questioning elicits the history of severe attack of chills and fever twelve years ago lasting six months; also that for over ten years she has noticed a swelling on the left side.

By exclusion the diagnosis is limited to either floating kidney; much enlarged, floating, hypertrophic spleen; or some form of omental or mesenteric tumor, not adherent to any of the abdominal organs, unless possibly to intestines, although there have been no symptoms to warrant the supposition. Symptoms and signs betoken considerable pelvic congestion. By the aid of her history, and chiefly from the shape and mobility of the tumor, I finally arrive by exclusion at the diagnosis of dislocated, hypertrophied spleen.

Patient at once put under active treatment for symptoms. No improvement, rather worse. Operation proposed.

Contraindications for operative interference:

1. The patient's general poor condition; the anæmia; the condition of her heart.
2. Disagreement of most of the consultants.

Reasons for operating:

1. Confidence in the correctness of diagnosis.
2. The danger of the pedicle becoming twisted, leading to death of the organ by gangrene.
3. Constantly increasing pain and sense of weight in the abdomen.
4. The pain is greatest when lying down, wherefore she is deprived of the needful rest and sleep.
5. The abdomen is tender to slight pressure over the area through which the tumor moved, and this tenderness has of late been rapidly increasing.
6. The pain is dull and heavy from pressure upon the pelvic organs, and there is probably a constantly maintained or increasing congestion of these organs.

---

[1] This operation was reported in December, 1886, but the details were not then published.

7. If so, this may lead to serious inflammatory troubles. But, even without acute inflammatory manifestations the congestion may be accompanied by or occasion plastic exudations, and if so, as in the case of more common forms of abdominal tumors, dangerous adhesions may be forming between the abdominal organs.

8. The spleen is not essential to life, as has been demonstrated before, other organs assuming either compensatory or vicarious functions where it has been removed. The percentage of recoveries after splenectomies for causes other than leucæmia has been fairly encouraging.

9. Absence of leucænia. A week before the operation the blood was examined by Professor Satterthwaite, who found it normal.

Operation submitted to.—The patient was prepared by acting upon her bowels with licorice powder, and sulphate and citrate of magnesia for about a week. She was toned up with good food, digitalis and brandy, etc., and all the emunctories made active. During the four hours preceding the operation enough brandy was given to stimulate her perceptibly. On the day before, by letting her, while in bed, raise her head to contract the recti muscles, I observed that the interspace between these diverged from the navel toward the pubis considerably to the left from the dark median line of the skin, and I took advantage of this discovery in making the incision.

The operation was performed November 21, 1886, with the kind assistance of Professor Hanks and Drs. Dudley and Molloy. Ether was used.

I made the incision from a little below the navel, downward and about four and a half inches long. Considerable bleeding. Kolberle's clamps were used. No vessels were tied. Plastic formations in the parietes made the entrance a little slow. The anatomical "layers" entirely lost. A director was used with difficulty. Peritoneum deeply congested, bleeding freely. The omentum long, lying over to the right, its left edge only showing in contact with the right end of the tumor but not adherent to it.

It occurred to me right here that I had made the mistake of making the opening below instead of above the umbilicus, unconsciously, perhaps, influenced by the fact that others did not agree with me in the diagnosis. But for this I probably should have made the incision high, to get at the base of the pedicle and also to lessen the possible chance of a subsequent ventral hernia. However, I knew that the pelvic organs were in a bad condition and might need attention, and this influenced my choice.

The tumor, being the spleen, was lying as diagnosed, hilum posterior, and was tilted out right end first entirely free from adhesions, but followed by its pedicle, exhibiting a vein so large that the first impression was that a coil of the small intestine had in some way become incorporated with it. The artery was the size of an ordinary lead-pencil, but the vein five or six times that size. The artery was straight, the vein varicose. There was very little tissue besides the peritoneal covering.

A heavy silk ligature was placed around the pedicle about three inches from the spleen, to test the tissues and the silk and to prevent spattering when severing the pedicle. Two of the assistants were asked to watch the pulse at the wrist on either side, and one of these had a clamp in position to grasp the pedicle above in case of cutting through of the ligature, which was now slowly tightened. The assistant on the right felt the pulse grow fainter at once, the one on the left noting no change. Eight or ten seconds after the maximum tension of the ligature was reached the assistant upon the right felt the pulse growing much weaker and the one upon the left now also noting a marked decrease in strength, not in rhythm. No change in the respiration. The change in the circulation, verified by all present, became so marked that for a brief moment I considered the wisdom of cutting loose the ligature, and if this restored the circulation going no further, but fortunately I kept on. Brandy, ether, and camphor were injected under the skin, and in a few minutes the heart regained strength. (Since then I have noticed that the patient's pulse upon the left is much stronger than on the right side.)

A heavy clamp was put on above the ligature; spleen, with about three inches of pedicle, cut away close below the clamp. Pedicle tied in two parts as high up as possible; clamps removed; stump trimmed; end of artery in stump tied with catgut; ligature ends cut very short and pedicle dropped back.

When the spleen was first lifted out I noticed a fair quantity of free fluid in the abdominal cavity. This I left there, expecting to act freely on the bowels after operation, and did not enter with a sponge. I used silk sutures for the would, including in them the peritoneum, as I have continued to do in my operations ever since, although I now use silk-worm sutures exclusively. I took particular care to unite the abdominal fascia with catgut, but did not treat the peritoneal edges similarly, as they rolled well together without it. The dressing was four layers of lint ten by six inches, impregnated with carbolized glycerine, and over this a thick layer of absorbent cotton covering the whole abdomen, and a flannel binder.

Before tying the pedicle it occurred to me, as it also was suggested, that by compression of the spleen a considerable portion of the blood in the gland might be forced back into the circulation and saved, but I desisted from so doing, not being certain of the condition of the parenchyma of the organ. It measured about seven and a half inches by nearly four and a half inches; two inches thick, and weighs a fraction less than two pounds. Time of operation, thirty minutes (guessed at). Owing to the shock I attempted no intra-abdominal examination of the pelvic organs.

She rallied soon from the immediate effects of the anæsthetic. There was a tendency to vomiting for two days, well controlled by small doses of hot water every fifteen minutes and by occasionally causing the patient to fill her stomach with warm water or tea, which gave rise to free momentary vomiting but insured rest for one or two hours after. She vomited a little blood now and then, and at such times complained of pain like needles piercing her side.

Two hours after the operation she suddenly began looking blue in her face, expressing at the same time a sense of great heat. Her pulse then beat at the rate of 108, but the temperature, taken by mouth, registered only 97$\frac{5}{10}$°. The brandy taken before the operation may have had something to do with this. About six hours after operation temperature rose to 100$\frac{4}{10}$°, the highest at any time. The only thing that gave us much trouble after this was her inability to pass urine unaided until the tenth day. The sutures were removed by the ninth day.

The stomach was rebellious for about two weeks, but after that she improved rapidly and grew fatter. The symptoms which marked her condition before operation reappeared now and then at irregular intervals, but gradually subsided. Sleeplessness and shooting pains remained longer than the other symptoms. The temperature rose to 100$\frac{4}{10}$° about six hours after operation, and for two days flucuated between this and 98°. After this it did not reach 100°.

Having no home the woman remained in the hospital until January 17, 1887, although she was well enough to be dismissed some time before that. She evidently became demoralized by the unwonted good care she had there received, and by the help extended to her after she left, for, although she improved steadily in appearance she refused even to try to work up to the time of her last visit, about eighteen months after the operation.

I was happily disappointed in not meeting with any of the grave sequences which I had been led to expect after the operation from the writings of Credé, Collier, Bryant, Spencer Wells and others. There was no secondary hemorrhage, no marked temporary anæmia, no sudden enlargement of the thyroid or other glands, no perverted appetites or sensations, no apparent disturbance in the functions of glands and organs supposed to assume the functions of a lost spleen, in short there was nothing remarkable in the patient's condition while convalescing, except what is referred to above.

A CONTRIBUTION TO THE STUDY OF HAY FEVER.

By J. M. W. KITCHEN, M.D.,
NEW YORK.

One would think that many propositions relating to hay fever should justly be considered as proven. Those who dispute them can hardly be judged to be thoroughly informed as to the observations and experiments already made, and which, with other evidence, are on record. But various points may still fairly be regarded as *sub judice*. Herewith I present observations and conclusions relating to sundry of these, some of which I believe are original, while others are in substantiation of opinions already expressed by other observers.

Every hay-fever case that I have studied seems to have had an exalted sensitiveness of those receptive centres that are in intimate communication with the intranasal surfaces. In many cases this appeared to be the only peculiar nervous condition present that could be considered as being related to the affection. Although such a condition may result from pathological causes and apparently is always present in hay-fever subjects, I cannot consider that it is necessarily a pathological state. In many cases it seems to be merely a higher development of the common property of receptive sensitiveness that is present in every normal individual, being analogous to the trained visual centres of the painter, the aural centres of the musician, or gustatory centres of the tea and wine taster.

In the great majority of cases I do not believe the nervous condition alone to be a sufficient cause of the disease—intranasal hyperæsthesia or vulnerability being also a necessity.

In most cases this exalted sensitiveness is not confined to the particular receptive centres referred to, but is a general condition that seems to be the natural concomitant of an exalted development of the intellectual centres. When the condition is not generalized I have quite frequently been able to trace the increased central activity to exaggerated intranasal or reflex irritations. In some cases a superficial observation would lead one to think that there was not any particular central receptive hypersensitiveness; but close study of cases, especially as to the details of their lives, and through inquiry of relatives, reveals this peculiarity. Such persons are likely to be unduly disturbed mentally by unusual causes, and to be morally sensitive. They bear pain badly. A mustard-plaster is terrible to them. The idea of an intranasal operation is intolerable.

I think it will be found that if a person is centrally receptively hypersensitive to moral and other irritations and does not have hay fever, his intranasal and adjoining mucous surfaces will be found so well nourished or otherwise structurally resistant as to be invulnerable to atmospheric hay-fever irritants, even though such surfaces may be in a pathological state in comparison with his other tissues. But if a person have non-resistant and structurally vulnerable tissues in these surfaces and does not have hay fever, he will be found to be devoid of this central receptive hypersensitiveness, even though he may be outwardly demonstratively nervous.

The great majority of cases that I have studied have had chronic intranasal disease of sufficiently marked a character to warrant the conclusion that the excitability of the centres must have been augmented, and that the property of nervous irritability in the peripheral parts affected had been greatly increased on that account. Such inflamed parts, besides being hyperæsthetic, are generally in an abnormal structural condition readily affected by the physiological, mechanical, and chemical action of atmospheric irritants. It will be remembered that pollen acts physiologically by the protrusion of its inner coat as an elongated process in the act of impregnation. It acts as a mechanical irritant on account of peculiar formation, especially when covered with sharp spines. Chemical irritation also occurs when it contains acrid principles. It is probable that the physiological action is performed when pollen is deposited on a sufficiently vulnerable nasal mucous membrane. Such conditions of vulnerability may be hyperæmic or anæmic. Marked malformations seem to be most frequently present, while chronic hypertrophic catarrh ranks next in prevalency. The malformed cases of evident congenital origin gave histories of attacks of hay fever running back beyond memory into childhood. Quite a number of cases refer the commencement of the attacks to periods shortly subsequent to the beginning of chronic catarrhs. A few cases were apparently due to extranasal causes, such as enlarged tonsils, peculiarities in the dental formation, etc., which had caused mouth-breathing, the result of which is, of course, loss of tone, due to insufficient intranasal stimulation from deficient nasal respiration.

I at one time thought that all cases of hay fever had local intranasal disease other than the specific attacks, but further research has demonstrated the contrary. A few cases—a very small minority—had no apparent local pathological condition during the intermissions; but these few cases had a possible structural cause, viz.—a thin, delicate mucous membrane seemingly deficient in connective fibres and epithelial covering, the vulnerability of which to special irritants could be readily imagined. This peculiarity extended as well to the skin generally of these cases. Many of them are particularly sensitive to those acrid, poisonous emanations that are given off from the *rhus* tribe of plants. All of those thin-skinned cases were centrally sensitive to a marked degree, so that no conclusion could be formed as to this structural condition being a sufficient cause without particular central exaltation. Probably this condition is the result of the generally poor and inharmonious nutrition of these individuals.

So far as I could ascertain, the diseased states referred to were mostly causes and *not* effects of hay-fever attacks. I have seen a number of severe cases of many years' standing whose nasal cavities during the intermissions were quite free from diseased conditions, though apparently vulnerable from structural causes. I do not think that hay-fever attacks alone would produce hypertrophic or other lesions to any great extent, as the remittent periods are so extended that the parts have ample time to return to the normal state. The attacks would, of course, aggravate ordinary catarrhal conditions already existing.

I cannot consider it scientifically correct to speak of hay fever as a *neurosis*, for it has not been shown that a *disordered* nervous condition, although a frequent predisposing cause, is essential. In a great majority of cases studied by me the nervous element was not sufficiently marked to warrant a belief that without concomitant intranasal hyperæsthetic conditions there would be susceptibility to irritation from plant-pollens and irritants of the like nature. The term neurosis is misleading, and at best only describes one predisposing condition. To be sure, most cases have marked general nervous peculiarities; but some few are not generally sensitive, and, in view of the great peculiarities of periodicity marking the disease and of the most prominent exciting cause, to speak of a predisposing cause as the disease itself is somewhat like playing "Hamlet" with the *Prince of Denmark* left out. The fact that hay fever occurs in many neurotic and hysterical subjects, though such morbid conditions of a nervous character in such individuals undoubtedly predispose to hay fever in many cases, I think has misled various observers into concluding that such conditions are essentials. I hold that they should be more justly considered as predisposing causes and aggravating complications. Every being differs physiologically from others in the degree of susceptibility to peripheral irritations, and various hay-fever irritants are strongly irritating. The bronchial mucous membrane may be a tissue having minor resistance to many direct and reflex irritations; but morbid attacks due to such causes are not denominated neuroses. Neither should irritative affections of other mucous membranes be so designated, especially when the periodicity of such affections can be absolutely shown to be coincident with the presence of atmospheric irritants, and their severity be shown to be in strict sequence to the amount of the special irritant present. Persons subject to hay fever have the common physiological property known as nervous irritability highly developed, and this is the only apparent essential idiosyncrasy of a nervous character, and I hold should not be called a morbid condition. Even the most healthy and nervously insensitive person, with the toughest tissues, could be given a periodic irritative nasal catarrh by an intelligent local application of a selected irritant at the proper time. One proof that an attack of hay fever is essentially an irritative catarrh of the parts principally affected is, that the first symptoms are of peripheral irritation. I have never met a case having so-called prodromic symptoms where these could not be referred to introspective anticipation, or to various depressing climatic and malnutritive non-neurotic disturbances. I have been surprised to find how many of these "nervous" patients have acknowledged uncertainty as to the exact day and hour of the attack. Many who believe in an exact date of the recurrence are mistaken. A formed habit might possibly account for some of these cases. The great majority say that this time varies somewhat, and that the period of its occurrence, as well as its severity, depends upon the peculiarities of the season and upon the general state of the health at the critical season or shortly before; depreciated general states of nutrition result in loss of tone locally, as well as a general increase of irritability, due to the larger blood-supply following weakened inhibitory centres.

I do not even consider that the beginning of an attack of hay fever should be considered as pathological; but only as a normal effort to expel objectionable foreign matter by sneezing and by an efflux of serum. I regard the ability of the nasal mucous membrane to suddenly pour out large quantities of serum as a physiological function, the office of which is to wash out excessive foreign matter that would naturally be liable to collect at the external extremity of the air-tract. I do not know that such an interpretation of this action has hitherto been made. In hay fever I consider this function to become pathological only after undue continuance.

Summarizing, I conclude that an individual may be susceptible to hay-fever attacks:

1. Because of local nasal and neighboring hyperæsthesia plus localized normal, central exaltation, without neurotic manifestations.
2. Because of local hyperæsthetic conditions plus generalized exaltation non-neurotic in character.
3. Because of local hyperæsthesia plus general neurotic conditions.
4. Because of normal local structural vulnerability plus general nervous abnormalities.
5. Because of general hyperæsthesia, centrally and peripherally (infrequent).
6. (Possibly) Because of peripheral hyperæsthesia plus localized central neurotic conditions.

Furthermore, I conclude that to designate as hay fever catarrhal attacks in nervous persons due to reflex and other causes than the atmospheric irritants produced by flowering plants, even if occurring in hay-fever subjects, is unscientific nomenclature.

OBSERVATIONS ON POLLENS DURING THE SEASON OF 1888.—Those specimens studied previous to June 10th were procured from Central Park, New York City; after that date, mostly from Gilmanton, N. H., which place has an elevation of 1,000 feet, a very dry and exceptionally pure atmosphere, peculiarly favorable to most irritable conditions of the air-tract, but only affording partial exemption from hay-fever attacks. Great differences exist in pollens as to their form, size, atmospheric buoyancy, and chemical properties. Some, like those of common garden-rhubarb and mignonette, are smooth. That of Indian corn is very large, is smooth, but does not float very readily in the atmosphere. The pollen of ragweed (*Ambrosia artemisiæfolia*) is quite small, is easily detached from the plant, floats in the air readily, and is covered with multitudes of minute very acute spines, looking not unlike a miniature chestnut-burr. The pollen of the golden-rod is small, covered with spines, and is shaped and looks like a small horse-chestnut burr; but this pollen is not so readily detached from the plant and apparently does not float readily. Although the plant is abundant at Gilmanton very little of its pollen was deposited from the atmosphere on my microscope-slides. I judge, on this account, as well as from the fact that golden-rods having pollens of the same appearance grow abundantly in exempt regions, that the pollens or other productions of this plant have little to do with hay-fever causation. I received specimens from locations extending from Cape Cod to Hillsborough, N. B. The most irritating pollen that I have studied is that of timothy-grass (*Phleum pratense*). Although not a hay-fever sufferer, and although I have a fairly healthy nasal mucous membrane, I succeeded in giving myself a typical attack of hay-fever by inhaling timothy-pollen freely—an attack which persisted twenty-four hours, and which was so distressing that I should seriously object to repeating the experiment. In a few seconds after the inhalation sneezing occurred, followed within less than a minute by a profuse discharge of serum. Only later was the deeper layer of the mucous membrane affected, it becoming swollen. It will be noted that this action differs from the commencement of an ordinary acute rhinitis due to "taking cold," where the swelling precedes the discharge. This is evidence of the peripheral character of the irritation in hay fever. Timothy-pollen is large, and when freshly collected from the plant has facets, looking somewhat like a grain of Indian corn. When moistened it immediately becomes symmetrically globular, and commences it physiological action by protruding a process from its periphery, around the inner extremity of which the fovilla in the pollen grain seems to accumulate. Later on this fovilla appears to escape through this process and is seen adhering to the external surface of the grain near the process. Ragweed grows in moderate quantities at Gilmanton, though of a stunted growth. Its flowering products were collected from the atmosphere in varying amounts—hay-fever patients being affected in direct proportion with the amount found to have been deposited on my slides. Of the clouds of dust that every breeze and touch detaches and carries from this plant during its flowering stage, only about one-fifth is pollen. The bulk of it is vegetable *débris*, such as cells, scales, etc., and this corresponds to the deposits from the atmosphere on my slides. This ragweed dust is a pungent irritant. The whole plant has a marked aromatic principle in its various parts. When shaken in the face, this dust causes immediate smarting and burning of the skin, of the conjunctivæ, and of the intranasal and pharyngeal mucous membranes. During the periods of fruit-tree and rose blooming a great amount of vegetable *débris* was in the atmosphere, but little or no pollens; and during those periods in which an abundant quantity of vegetable matter was present in the atmosphere, I noticed a distinct tendency to local irritations in those suffering from bronchitis and rhinitis who were not hay-fever patients. I therefore conclude that vegetable *débris* of various kinds, especially when of an aromatic pungent quality, may be considered, with pollen, an exciting cause. I did not find any grass-pollens, other than a few timothy-grains, on my slides at any time. This may have been due to the exceptionally dry character of the early part of the season. The day after a light frost I did not collect any perfect pollen on my slides, the grains being ruptured and spineless. Pollen collected from the plant at the same time preserved its form, but the spines were imperfect. Fresh pollen, exposed dry to an all-night severe freezing, with a salt-and-ice mixture, was blackened, somewhat changed in shape—wilted, as it were—and the spines destroyed. The same pollen, moistened and under the same circumstances, loses its identity, becoming mere masses of granular matter. The form was preserved in some, excepting that their peripheries showed a row of round granules instead of sharp spines. I conclude that pollen in a damp, freezing atmosphere is destroyed, and becomes innocuous so far as its physiological and mechanical capabilities of irritation are concerned. The plant is, of course, destroyed by hard frosts as well as by heavy rain-storms. No pollen or vegetable *débris* was deposited on the slides immediately after rains. Here, then, is probably seen the cause of relief experienced by sufferers after hard frosts and after rains.

A study of the peculiarities of certain localities reputed to give exemption from hay-fever attacks seems to show that the exemption is due partially to the favorable effect produced on the general nutrition of patients, as well as on the local parts, by change of scene; favoring conditions of altitude, amounts of atmospheric moisture, moderate degrees of heat, and general purity of the air. But diminution or entire absence of pollen and vegetable *débris* in the air breathed is the great peculiarity of exempt localities; and after all allowance is made for the nervous, local hyperæsthetic, and other elements, irritation or poisoning by plant-products is the great etiological factor that is pre-eminent in hay fever. The absence of pollen, etc., may be due to a variety of circumstances; *e.g.*, California is exempt because the long dry season is unfavorable to the production of pollen and other flowering products. Europe is exempt late in the season because these inimical weeds do not grow there that are so abundant in most parts of the United States. England has a favorable climate for the flowering of the grasses during early summer, while the reverse is the case with us, our hot, dry, and variable climate affording us comparative freedom from the exciting cause at that time. The White Mountain resorts owe their immunity to the facts that they are located in the centres of very large regions which produce little of the irritating plant-products, and also that they are situated in the lee of high hills, the windward slopes of which intercept and hold such irritants as fall from the higher atmospheric currents and which may have been borne from far-distant sources.

ABDOMINAL PRESSURE IN HYSTERIA.—Dr. A. M. Dokhman, in a note communicated to the *Russkaja Meditsina* on the arrest of hysterical paroxysms by pressure on the ovary, points out that the treatment is by no means new, as blows on the abdomen used to be administered by means of iron instruments in the Senmedarski epidemic, and were employed very largely by Goltz as early as 1727. He suggests that, although pressure is made over the region of the ovary, it does not appear that the ovary has much to do with the effect produced, for similar pressure is efficacious where no ovary exists—that is to say, in male patients. He is disposed to compare the effect to that produced by compression of the carotid artery, which will sometimes arrest a paroxysm, and he suggests that the sudden stimulation of the splanchnic nerves may produce an alteration in the vaso-motor relations, and in this way may cause the arrest of the paroxysm.—*The Lancet.*

VIGIER'S CORYZA POWDER.—This powder is composed of equal parts by weight of pulverized starch, boracic acid, and tincture of Siam benzoin. Care must be taken to see that the tincture of benzoin, and not the powdered gum, is used, as the former by its evaporation leaves a finer powder, that does not cake like the pulverized gum.

SUCCESSFUL LUMBAR COLOTOMY, WITH SPHINCTER FORMATION, IN A CASE OF CONGENITAL ABSENCE OF RECTUM AND ANUS.[1]

BY GEORGE E. BREWER, M.D.,
NEW YORK.

THE following case of congenital malformation, involving the rectum and anus, recently came under my observation.

Mrs. S——, of Block Island, R. I., was delivered, on July 5th, of a well-nourished and apparently healthy male child.

Fifty-two hours later, at the request of the attending physician, Dr. C. H. Hadley, I saw the child in consultation.

The mother stated at that time that, although the child had nursed almost constantly since its birth, there had been no discharge from the bowels; that during the past twelve hours there had been noticed a marked restlessness, a gradual distention of the abdomen, and a slowly increasing lividity of the skin. In reply to questions, she further stated that there had been no vomiting, and that the urine had been passed normally.

An examination of the perineal region showed not the slightest trace of an anus, the skin extending from the scrotum to the coccyx in an unbroken outline. There was, however, a slight thickening of the raphé midway between these two points. Pressure over the abdomen gave no visible or palpable impulse in the perineal region. An aspirating needle was introduced in several directions, with negative result.

I stated to the attending physician that, in my opinion, we had to do with a case of imperforate anus, but that the lower portion of the rectum could, in all probability, be found within the pelvic cavity; and advised an exploratory perineal operation on the following morning, with a view to finding the rectal pouch and, if practicable, to establish an outlet in the normal position; if in this we were unsuccessful, to open the colon in the left lumbar region. An exact statement of the child's condition, and of the nature of the operation, was made to the parents, who were left to decide the question of operative interference; and although the chances of recovery, in case the colotomy was found to be necessary, were roughly stated to be but one in ten, their decision was favorable, and they readily consented to any operation which would offer hope of saving the child's life.

On the following morning, therefore, assisted by the attending physician and Dr. Frederick H. Hoadley, of this city, I undertook, without an anæsthetic, the exploratory perineal operation. An incision was made in the raphé of the perineum from the base of the scrotum to the coccyx, and the various structures of the pelvic outlet divided layer by layer, care being taken not to wound the urethra or bladder, the exact position of the former being indicated by a previously-introduced gum-elastic bougie.

During the progress of this dissection frequent attempts were made to detect an impulse, caused by the crying of the child, or pressure made over the abdomen, which would indicate the presence of a blind rectal pouch. The result of these examinations was, however, always negative. After the perineal incision had been carried to a depth of nearly two inches, so that the thin layer of tissue separating the pelvic cavity from that of the abdomen moved freely with each respiration, an examination was made by each one present to determine, if possible, any sign which would indicate the presence of the blind extremity of the gut. The entirely negative result of this examination led me to abandon further search in this locality, to close the wound antiseptically, and to attempt to find the colon in the lumbar region.

The child was placed on the right side, and the left lumbar region exposed and made prominent by means of a folded sheet placed underneath. An oblique incision was made, three inches in length, parallel with the last rib and midway between it and the iliac crest. This included the skin, superficial fascia, and a thin layer of adipose tissue. The underlying structures were then carefully divided on a director until the transversalis fascia was reached. Through this could easily be distinguished the distended colon pressing against the outer border of the left kidney. The fascia was next divided and the kidney pushed aside, the colon then presented in the wound, and that portion which is free from peritoneum, lying between the two lateral longitudinal bands of muscular fibres, was easily transfixed with a needle and drawn to the external surface of the wound. Here the gut was united to the skin by two rows of sutures, three on each side. A longitudinal incision was then made into the bowel, midway between the two rows of sutures, and a large amount of meconium evacuated. The external wound was then closed to the border of the intestinal opening, and a dressing of absorbent iodoform gauze applied. It may be added that after the bowel had been opened, a probe was passed downward to determine the length of the blind extremity of the gut, which was found to be about two and a half inches.

---

[1] Read by invitation before the Surgical Section of the New York Academy of Medicine, November 12, 1888.

The immediate effect of the operation was a marked relief from the abdominal distention and a noticeable change for the better in the color of the skin. As soon as the spontaneous discharge of meconium ceased, the child was placed in a previously warmed bed, and within ten minutes was sleeping quietly. An hour later he awoke, appeared hungry, was placed at the breast and nursed vigorously, after which he again slept quietly for several hours.

The operation was followed by only a slight reaction, the temperature on the second day reaching 101°. There was a slight redness and inflammatory induration about the lumbar wound, which subsided when the dry dressing was changed and a flaxseed poultice applied. The perineal incision healed by first intention, and the sutures were removed on the sixth day.

An interesting feature of the case was the prolapse of the opposite wall of the intestine through the incision. A tendency toward this was noted at the time of the operation, but was thought to be due to the great intra-abdominal distention. On the following day a nodule appeared at the orifice of the wound, which gradually increased until a T-shaped portion of inverted intestine lay on the external abdominal surface. At either end of the cross piece was an opening; the upper. connecting with the transverse colon, extended only about half an inch from the wound, while the lower, leading to the blind extremity of the bowel, extended from this point nearly two inches. Each of these openings was closed by the sphincter-like action of the double layer of circular muscular fibres present in the prolapsed portion. At first attempts were made to reduce this prolapse, until it was found that the muscular contraction at the upper orifice served to prevent a constant discharge of fæcal matter; and that, while ordinarily closed, it was easily overcome by contraction of the abdominal muscles. The prolapsed portion was therefore allowed to remain in place for eight weeks, to insure a firm union between the peritoneal surfaces; when the lower portion, connecting with the blind extremity, was ligated off, leaving only the upper opening connecting with the transverse colon. I was obliged to leave the island two days after this last operation, and have not since seen the patient. Dr. Hadley, however, informs me that the child is in excellent health, although another slight protrusion occurred after the strangulated portion had sloughed off.

From the day of the operation the child never presented an unfavorable symptom; it gained rapidly in weight, slept well, and was noticeably free from the ordinary stomach and bowel complaints occurring in children of that age.

The rarity of such malformations, and the rather more than ordinary success which attended the operation for relief in this instance, led me to careful study of such cases as presented by surgical authors. Regarding the frequency of congenital deformities about the rectum and anus, Cripps,[1] reviewing the statistics of a large number of observers, gives the average as 1 in every 4,500 births. Gay,[2] in an analysis of 104 cases of such malformation, notes entire absence of rectum and anus in eight cases, or about 8⅓ per cent.; while Bodenhamer,[3] in his tables, which include 285 such cases, refers to 28 in which the rectum was entirely absent, or about ten per cent. of the whole number.

If these statistics can be relied upon, cases similar to the one which I have reported may be expected once in something over 4,500 births.

In a discussion upon the etiology of imperforate bowel, Geraldès[4] calls attention to the fact that in early fœtal life the intestinal canal is blind, its lower portion communicating with the atlantois, which afterward enters into the formation of the bladder and urethra. At a later period of development this communication is shut off, and the rectal pouch descends to meet and become continuous with the anal depression. Arrest of development may result in absence or malformation of either rectum or anus, or of both combined, and may take place at a time before or after the separation of the intestinal from the genito-urinary tract has been effected. As a result, therefore, we may have many varieties of malformation, which have been classified by Curling as follows:

I. Simple stenosis of the anus.

II. Imperforate anus without deficiency of rectum.

III. Imperforate anus, the rectum being wholly or partly absent.

IV. The anus opens into a cul-de-sac, the rectum being partially absent.

V. Imperforate anus in the male, the rectum being partially deficient, communicates with the urethra or bladder.

VI. Imperforate anus in the female, the rectum being partially deficient, communicates with the vagina or uterus.

VII. Imperforate anus, the rectum being partially deficient, opening externally in an abnormal situation by a narrow outlet.

Regarding prognosis little need be said. It is evident that cases in which total obstruction is present lead speedily to a fatal termination, the only recorded exception to this being the case, cited by Cripps, of a child, aged thirteen, who obtained relief every three or four days by copious vomiting of fæcal matter.

The cases also in which relief is attempted by surgical interference show a death-rate far above that shown by cases where the cause of interference is other than a congenital malformation.

Cripps, in 1882, reported 100 cases where operations were undertaken for the relief of imperforate bowel. This list includes all the recognized operative procedures, *i.e.*, simple puncture, perineal incision, with or without excision of the coccyx, recto-vaginal fistula, inguinal and lumbar colotomy. Of his 100 cases, 50 resulted fatally. The highest death-rate occurred in cases where simple puncture was employed. Of the 17 cases so treated, 14, or eighty-two per cent., died. The lowest mortality occurred in those cases where relief was afforded by the establishment of a recto-vaginal fistula. This was reported in 14 cases, with but one death. The percentage of deaths following perineal incision was 36.0; following inguinal colotomy, 69.0; lumbar colotomy, 66⅔.

The advisability of further operative interference in cases where the establishment of an outlet in the perineal region is found to be impossible, has been seriously questioned by several surgeons. Bigelow,[1] in a discussion which followed the reading of Dr. Gay's paper, pronounces emphatically against it; and Gross, in his "System of Surgery," goes so far as to say that "he is struck with astonishment that anyone possessed of the proper feelings of humanity should seriously advocate a procedure so fraught with danger, and followed, if successful, by such disgusting consequences." Few surgeons, however, entertain such extreme views, and most are willing, especially if the parents desire it, to render in such cases what small measure of relief the resources of their art afford.

[4] Nouveau Dictionnaire de Médecine et de Chirurgie.

Limiting the consideration of treatment to those cases in which the establishment of an artificial anus in the perineal region is impracticable, two methods of procedure present themselves for choice, namely, inguinal and lumbar colotomy. The idea of opening the colon at the sigmoid flexure and establishing a permanent outlet in the inguinal region, was first suggested by Littré in 1710. As his method involved an opening into the peritoneal cavity, the mortality resulting from this operation, before the days of aseptic surgery, was very great. Toward the close of the eighteenth century Callisen suggested the plan of tapping the colon in the left lumbar region, without opening the peritoneum. In three excellent memoirs upon the subject, Amussat reviews with unfavorable comment the twenty-one cases of Littré's operation performed up to that time, and recommends, with a slight modification, the operation of Callisen.

He reports four cases in which he operated, three of which were successful, and establishes, for a time at least, the superiority of the lumbar over the inguinal operation.

The reaction from this opinion began with the publication of Bodenhamer's exhaustive treatise upon the subject. This author, reviewing the histories of all the cases which he was able to collect up to that time, pronounces mildly in favor of the inguinal operation. Since that time writers have become gradually more emphatic in the expression of their views, until at present the weight of modern authority[2] is overwhelmingly in favor of the operation of Littré.

In determining which of two operations should be chosen to afford relief in a case of this kind, attention should be directed, first, to the difficulties attending each procedure; second, to the resulting inconvenience to the patient; and third, to the mortality, which can only be determined by an analysis of a large number of cases.

Regarding the first of these considerations, it may be fairly stated that, while neither method presents insurmountable difficulties, the inguinal is rather more simple than the lumbar. In either event the resulting inconvenience to the patient may be great, and neither operation offers any special advantage.

Concerning the question of mortality, we have no accurate data. Several attempts have been made to tabulate the cases with a view to determining this point, but the results have been incomplete, and the number of cases too small to furnish reliable information.

In reviewing the literature of the subject, including the tables of Amussat, Bodenhamer, Gay, and Cripps, I have been able to collect 73 cases, of which 56 were inguinal and 17 lumbar colotomy. Of the former, 21 were successful, while 35 died; of the latter, 8 recovered, and 9 died. The mortality in the cases where Littré's operation was employed was 62½ per cent.; in those where the operation of Amussat was made, fifty-three per cent.

While the number of cases is not sufficient to settle the question, it clearly shows that the advocates of Littré's operation in such cases have not, at least from a statistical point of view, established beyond controversy the superiority of their method.

RHIGOLENE FOR MUSCULAR SPASM.—In a case of spasmodic contraction of the left trapezius muscle, in which the circle of ordinary remedies had been tried in vain, Sinkler used the rhigolene spray. In two weeks most marked improvement was noticed. Weir Mitchell has used this treatment successfully for spasm of the facial muscle. Be careful not to apply the spray too long, as an ulcer has followed three-quarters of a minute's spray.—*Medical Times.*

A CASE OF SCIATICA TREATED WITH LARGE DOSES OF ANTIFEBRIN.

By AUSTIN FLINT, M.D., LL.D.,

PROFESSOR OF PHYSIOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK; VISITING PHYSICIAN TO BELLEVUE HOSPITAL.

M. G——, aged twenty-five, laborer, was admitted to Ward 19, Bellevue Hospital, August 14, 1888. The family history was negative. As regards the previous history there is nothing special to note until about a year ago, when the patient had pain, with soreness and tenderness, at the back of the right thigh, extending as far as the knee. This became so severe that he was compelled to keep the bed for two or three weeks. Under treatment at that time he improved, but has not been entirely free from pain since.

For the past three weeks the pain has been so severe that the patient has been confined to the bed most of the time. He has been treated with blisters, iodine, and a variety of internal remedies. Electricity had been tried before his admission to the hospital, but this gave on relief.

August 16, 1888.—The right leg was buried in flowers of sulphur for thirty-six hours. The patient said the pain was "perhaps a little better" after this application.

August 18th.—Sulphur was again applied for forty-eight hours, but without relief. At the end of that time the urine had a distinct odor of hydrogen monosulphide.

August 25th.—The patient was brought under the influence of ether, and the nerve was stretched by forced flexion of the thigh. This gave no relief.

August 26th.—I requested Dr. Rutson Maury, the house-physician, to administer antifebrin in as large doses as could be borne, watching the patient carefully. This treatment was carried out even more vigorously than I had expected. At 11 A.M., Dr. Maury gave twenty grains of antifebrin; at 1 P.M., fifteen grains, and at 3 P.M., fifteen grains, making in all fifty grains within four hours. The patient became somewhat cyanotic, and a half-ounce of whiskey was given with the last dose.

August 27th.—The pain was nearly, but not entirely, relieved, and the antifebrin was given again in the following doses: 10 A.M., twenty grains; 12 M., twenty grains, making forty grains within two hours. It was not necessary to give whiskey.

August 28th.—The pain was completely relieved, and the patient walked about the ward without difficulty. The large doses of antifebrin taken on August 26th and 27th had no unpleasant effects, and the patient expressed himself as feeling perfectly well, absolutely free from pain, and able to move about as he did a year ago, before he was first attacked.

August 31st.—The patient was discharged. He insisted on leaving the hospital to go to work. He promised, however, to report himself in case the pain should return. At the date of writing (November 12, 1888) no report from the patient has been received.

The treatment with flowers of sulphur was tried in accordance with a suggestion quoted from Guéneau de Mussey, in the *Therapeutic Gazette*, April 16, 1888, page 276. This suggestion was followed out efficiently. The parts were covered with flowers of sulphur spread upon a cloth, and the characteristic odor of hydrogen monosulphide was recognized in the urine after the second application.

Guéneau de Mussey recommended that the application be continued for twenty-four hours. I have since learned that this treatment had already been tried in the hospital, but without satisfactory results.

In the treatment that was finally successful, I intended to push the antifebrin to the extreme limit of safety, which, apparently was done, and certainly, in this case, with entirely satisfactory results, although it was thought necessary to administer these large doses carefully, and to watch the patient very closely.

Clinical Department.

MALARIA IN A DOG.

By THOMAS DARLINGTON, M.D.,

KINGSBRIDGE, N. Y.

So much has been written and said of late in regard to diseases that animals have in common with man, that I thought the following case might be of interest to some of the profession.

Recently I was asked to see a dog, belonging to a lady in a family that I usually attend, and found the following history of symptoms:

On Tuesday he was taken, while in the house in the sitting-room, with a violent shaking. After this passed off, he seemed very hot; and toward morning was wet with sweat. During that day he seemed somewhat listless and indifferent to tramps, etc., in which he had previously taken a decided interest.

The following day, at 6 P.M., the previous symptoms of shaking, heat, and sweating were repeated, and again on Saturday, and also on Monday he was taken in the same manner; each time one hour sooner.

I did not use the thermometer, as I am not familiar with the normal temperature of dogs. On the following day—Tuesday—I ordered for him sixteen grains of quinine, four grains every three hours, which he took and retained. The next day there was no return of the fever; but for several days he seemed listless and did not have his customary vigor. So I ordered Fowler's solution, four drops, t.i.d., and within a week he was all right again.

November 19, 1888.

ACTION OF SULPHATE OF SPARTEINE.—Professor Levascheff has completed an experimental study on the action of sparteine, from which he concludes (*The Therapeutic Gazette*) that the sulphate of sparteine has incontestably the property of reinforcing and regulating the contractions of a feeble or arhythmic heart, while at the same time slowing the pulse if that should be accelerated. Sparteine increases the blood-pressure, and causes the disappearance of symptoms of blood stasis and œdema, thus acting favorably on diuresis. The respiratory movements, under the influence of this remedy, become slower and more regular. Clinical studies have not yet determined a diuretic action for sparteine, and it is not yet known as to whether it possesses any direct action on the renal epithelium. Sparteine is less active than the other cardiac tonics—digitalis, adonis, and strophanthus. In inveterate cases, where the heart-muscle shows symptoms of degeneration, or where œdema is very excessive, sparteine is without effect, even although the other cardiac remedies may act in a more or less favorable manner. Sparteine is indicated in recent cardiac affections, when compensation is but little disturbed, and when the degeneration of the cardiac muscle is inconsiderable. Sulphate of sparteine has a decided and yet not transient action on the heart, but this action is too feeble to produce well-pronounced therapeutic effects. Sparteine acts very rapidly, fifteen minutes being sufficient to produce its characteristic action. Thanks to this rapidity of action sparteine has a certain value in cases of acute enfeeblement of the action of the heart, as is often observed in different infectious diseases. Small quantities of sparteine (three-fourth of a grain daily) produced a therapeutic effect, but pronounced and constant action is not procured with doses smaller than from two to five grains daily. Larger doses do not produce more marked effects. The daily dose of sulphate of sparteine should be from three-fourths of a grain to five grains, taken in three or four doses. The inconveniences of sparteine are irritation of the mucous membrane of the intestine, and, as a consequence, diarrhœa, vomiting, and nausea.

Progress of Medical Science.

Engorgement of the Spleen in Pneumonia.—According to the Berlin correspondent of the *Medical and Surgical Reporter*, Professor Gerhardt, of Berlin, has published a study on the engorgement of the spleen in pneumonia. He examined twenty-five cases for the above purpose, and found that in seven cases there was no swelling of the spleen; in six the engorgement was noticeable only in the early phases of the affection, while in ten cases the splenic tumefaction lasted throughout the course of the fever. The important point of the study is, of course, Gerhardt's conclusion regarding the pathogenesis of this symptom. He believes that the actual cause of the engorgement of the spleen in pneumonia does not depend upon febrile processes, nor upon microorganisms, but upon an aggregation of broken-down red and white blood-cells in the spleen—a view that is confirmed by certain other appearances in the affection, such as peptonuria and grass-green stools.

Aneurisms and Tubercle Bacillus.—In a paper read before the Academy of Medicine, M. Germain Sée stated that he had been struck by the fact, especially since the discovery of the tubercle bacillus, that patients suffering from aneurism of the aorta often become tubercular, and die of pulmonary phthisis, attended with the formation of cavities, and progressing slowly without fever. This had been observed by Stokes, and numerous instances can be found in the records of pathological societies. Out of twenty-four cases of aneurism under his own care, seven were thus affected with pulmonary tuberculosis. It is now well known that patients with cardiac affections are not exempt from phthisis. M. C. Paul has demonstrated the frequent occurrence of phthisis in cases of narrowing of the pulmonary artery. Aortic aneurism must now be considered one of the agents favoring the development of the tubercle bacillus. In aneurism, from the disturbance of the circulation, there is a stagnation of the venous blood, and diminished activity of the gaseous exchanges between the gases of the blood and those of the atmosphere. In this internal gaseous medium (in the alveoli of the lungs and smallest air-passages) the bacillus appears to multiply when it enters the body by the respiratory tract. In aneurism the air is imperfectly renewed in the whole of the lungs, just as in normal conditions it is imperfectly renewed in the apices as compared with the rest of the lungs. In short, excess of oxygen hinders, deficiency favors, the development of the bacillus. In this way the multiplication of the bacillus is accounted for; the way in which it penetrates into the pulmonary parenchyma in patients of all ages who are affected with aortic aneurism, remains to be shown. Lately it has been found that ulcerative endocarditis, or even simple endocarditis, with vegetations, is caused by a staphylococcus; rarely by a streptococcus; more rarely still by the tubercle bacillus. The analogies between endocarditis and endarteritis allow us to suppose the existence of an endarteritis, due to the presence of a microbe. Are the lesions that affect the internal and middle coats of an artery which has undergone aneurismal dilatation, caused by a bacillus? If this question is answered in the affirmative, one can easily explain how the bacillus is washed away from its position in the aneurismal wall to the lung, and there multiplies. In the treatment of aneurism, M. G. Sée relies on iodide of potassium; its mode of action he explains as follows: 1. It relieves the dyspnœa due to catarrhal affections of the bronchial tubes by liquefying the effused secretions. 2. It aids the intra-pulmonary circulation, and diminishes venous stagnation. 3. The volume of the aneurismal tumor is diminished by contraction of the adventitious coat and the tissues surrounding it. 4. By reducing the size of the tumor, the pressure on the adjacent nerves is relieved, and pain therefore mitigated. M. G. Sée gives the iodide in the amount of thirty grains daily, divided into three doses, to be taken at the beginning of a meal. For the relief of pain he has found subcutaneous injections of antipyrin most efficient. When a cardio-vascular tonic is required, he has obtained good results from sulphate of sparteine, and rejects altogether caffeine and digitalis.—*The Bristol Medico-Chirurgical Journal.*

Pyridine.—M. de Renzy has come to the following conclusions about pyridine: Internally administered, in doses of from 6 to 10 drops in water, it is well borne; it increases the strength of the cardiac contractions and diminishes the sensations of anxiety and oppression; it diminishes the number of cardiac pulsations and also the respirations; the blood-pressure is raised. Pyridine has regulated an irregular pulse. It is very valuable in angina pectoris and in cases of cardiac failure.

Phlogogen Secreted by Germs.—M. Arloing has made observations on a phlogogenic matter secreted by certain microbes, especially those of contagious peri-pneumonia cultivated on bouillon of sterilized beef and on potato. (*The Lancet.*) In cultures on gelatine at 113° F. this microbe secretes a substance which, injected into the connective tissue, excites inflammation and fever, often followed by death. In the exudation this phlogogen is found again in abundance. The liquid has the appearance of a citrine-like serosity, and, treated with absolute alcohol, gives a white clot-like precipitate which is easily redissolved in water. Obtained in a state of purity, it presents a yellowish aspect in the dry state, and a viscous consistence if still liquid. The chemical characters of this substance are similar to those of the diastatic ferment, pepsin. In contact with cane-sugar, it gives a precipitate with the cupro-potassic solution. Animals do not secure protection by injections of this phlogogen, since the same series of events occur in the same animal, no matter how many times the material may be injected. But some animals—*e.g.*, rabbits and guinea-pigs—enjoy a specific immunity from its effects.

The Development of the Fœtus.—Dr. La Torre has published his views on this question. His conclusions differ in many respects from those of previous observers. He believes greatly in the influence of the father's health and strength on the development of the child. He maintains that the sex of the fœtus has no influence on the development of the fœtus itself. The height, weight, and health of the mother do not, according to Dr. La Torre, influence the growth of her offspring. In respect to the health of the father, it is his height, breadth of shoulders, and cranial development which chiefly influence the development of the fœtus. When the father is in ill-health, locally or generally, the fœtus is much affected, especially in weight. Dr. La Torre declares that the sex of the fœtus depends greatly on the health and strength of the father; healthy fathers begetting more sons than daughters; sickly fathers more daughters than sons. He insists that multiparity alone does not exercise on the development of the fœtus an influence sufficiently marked to justify the clinical importance hitherto attributed to it. If there be any influence at all, it disappears entirely before the hereditary influence of a sickly father. When the father is healthy, the most favorable age of the mother for the development of the fœtus is from twenty-five to thirty-four; but, when the father is sickly, the age of the mother has no influence on fœtal development. The length of the fœtus is more in relation to its weight, and less in relation to the age of the mother, than is generally supposed, especially by those who rely on Dr. Duncan's statistics.—*The British Medical Journal.*

Atrophy of the Inactive Mammary Gland.—Throughout the Swabian Bavarian tableland the rate of infant mortality is very high, chiefly on account of the almost universal practice among peasant women of bringing up children by hand. Dr. Altmann has discussed this subject in an inaugural thesis. He finds that the custom arises from the deficient secreting power of the mammary glands of the mothers. He carefully examined the glands of thirty Bavarian women, between fourteen and fifty years of age, noting the weight of each gland, with and without fat, and the character of the glandular tissue, and its relation to the connective tissue around. He compared the specimens with four pairs of glands from Silesian women, who, almost invariably, suckle their own children. According to Hennig's researches, the weight of the mamma should range from 160 to 556 grammes (454 grammes = 1 lb. avoirdupois). Out of 29 mammæ from Bavarians only 8 exceeded 100 grammes, but it is known that the smallest breasts in healthy women are the best for suckling. On examining the mammary tissue from Bavarian nulliparæ and mothers who had never suckled, and comparing the samples with sections from Silesian nulliparæ and sucklers, Dr. Altmann found marked elements of difference. In the Bavarian specimens the ducts were scanty and the acini ill-developed; the connective tissue abundant and dense; in the sections from the mammæ of Silesians the glandular tissue was well developed, with a plentiful vascular supply, and the connective tissue loose and relatively scanty. Dr. Altmann traces the atrophic condition of the mammæ in Bavarians to the disuse of the gland, owing to the custom of rearing children by hand, which has prevailed for many generations. The atrophy has become hereditary. No doubt a far larger series should be examined in order to prove the accuracy of the above researches.—*The British Medical Journal*, October 6, 1888.

Large Congenital Ovarian Tumor.—Mr. Alban Doran, at a late meeting of the Pathological Society of London (*The British Medical Journal*, October 20, 1888), exhibited a pair of ovarian tumors, removed after death from an infant, which survived its birth but a few minutes. Mr. C. Hooper, of Aylesbury, who attended the case, reported that the infant's abdomen was distended with ascitic fluid and the superficial veins were engorged, as in malignant tumors of the ovary in the adult. Each tumor looked like a cystic kidney when fresh, and consisted of a single cystic cavity surrounded by a thin wall composed of a highly reticulated tissue. The trabeculæ, which traversed this tissue in all directions, were composed of collections of round cells in a transparent matrix, an arrangement recalling the structure of the inter-follicular tissue of the ovary in the earlier stage of fœtal life than that which this patient had attained. The growth appeared to represent persistence and hyperplasia of the entire embryonic tissue of the parenchyma of the ovary rather than round-celled sarcoma, which, even when congenital, was in every respect of a different character, as proved by a recent case described by Dr. John Phillips. Graafian follicles were found in the substance of the tumor, which, therefore, originated in the ovarian parenchyma and not in the hilum, but the tumor was clearly of extra-follicular origin. The cavities and the large central cyst appeared to be the result of breaking down of the tumor substance; they bore no epithelial lining. The tumors thus bore no resemblance to the common multilocular ovarian cyst.

The Weakening of Virulent Bacteria and Acquired Immunity.—A series of articles on this topic have recently appeared in the *Zeitschrift für Hygiene*. The introductory article by Flügge is an attempt to place the processes of weakening and immunity on a scientific basis, and it is owing to his labors, and, in fact, under his direction and advice, that other work in the same direction, that finds its memorial in the same number, has been carried on. Dr. Smirnow, of St. Petersburg, one of the co-workers under Flügge, discovered that not only was there a loss of a specific quality, but an actual general degeneration of the excitors of disease, which found expression in a diminished power of resistance against injurious influences. In general the susceptibility to the action of disinfectants rose in proportion to the degree of weakening, *i.e.*, the highest degree of virulence was associated with the highest resisting power against disinfectants.

Dr. Sirotinin, also of St. Petersburg, directed his attention more particularly to the part played by the products of tissue changes of bacteria in arrest of their development and the so-called retention hypothesis. The view is very widely extended that recovery from infective diseases and immunity against recurrences are due to the products of the tissue changes of the bacteria themselves, that the tissue changes of the schizomycetes cause their own death, and that they are at the same time a certain degree of protection against reinfection. His researches in elucidation of the question demonstrated that *outside* the organism free acids, excess of alkali, and carbonic acid cannot be retained for long in the living body. He found no support for the retention hypothesis, and concluded that within the living organism bacteria formed quite different products of tissue change from what they do outside the body.

Bitter, of Breslau, took up the next stages of the question: What are the products of tissue change produced by bacteria within the system? and is the continued development of bacteria, after invasion has once taken place, arrested by failure of nutrient supplies? As regards common forms of disease, anthrax, swine fever, and fowl cholera, he was able to give the definite answer that these diseases do not die out from exhaustion of the nutrient fluids. For those diseases that leave immunity against further attacks behind them, the exhaustion hypothesis was absolutely without support. As likely to throw light on the *modus operandi* of immunity from preventive vaccination, the same worker, Dr. Bitter, has studied the immediate changes set up by vaccination, the special points of interest being, where and to what extent the weakened inoculated bacteria develop, what temporary and permanent changes they set up at the point of insertion or throughout the whole body, whether the protection is absolute or conditional, whether the choice of points of entrance and the number of them are of importance. He has limited his inquiries to splenic fever, and by concentrating his powers has made some little advance. He at first ascertained that the development of weakened anthrax bacilli in the body of the sheep was very limited, extending very little beyond the region of the point of inoculation. Their absence from the organs and blood, which was determined with certainty, was in favor of neither the retention nor the exhaustion hypothesis. The animals thus experimented on showed, by-the-by, that they were completely protected.

The two next articles relate to the so-called phagocytes of Metschnikoff, and the supposed germicidal influence of the animal system. The phagocyte theory has met with a considerable amount of favor. This, shortly stated, is that the white blood and other meso-dermal cells devour and digest pathogenic bacteria entering the body. As some bacteriologists, notably Baumgarten and Weigert, have raised objections to this, it became of importance to determine the preliminary question: Do phagocytes digest bacilli, and are they the only tissues that do? If a portion of the bacilli that enter the system die off or are destroyed before coming into contact with the phagocytes, not only is the importance of the latter rendered doubtful, but the assumption is not remote that they destroy only degenerated bacilli, that they are only "crematories," as it were. The researches showed that the leucocytes took in and devoured "large quantities" of splenic fever bacilli; but, on the other hand, quite as many, if not more, became completely degenerated outside the phagocytes. This fact, which was determined with certainty both on frogs and warm-blooded animals, led to the assumption that the moment inimical to the bacilli was really to be sought in the fluid around the cells. This assumption rises in probability from the fact further ascertained that in fluids poor in leucocytes, such as the fluid from the pericardium and the aqueous humor, degeneration of the bacilli rapidly sets in. It still remains to be seen what the agent destructive of bacilli is.—*The Medical Press.*

Sixty Cases of Cerebral Paralysis in Children.—These patients were observed by Dr. Lovett during a period of four years. Twenty-six of them were cases of hemiplegia—half of the right side and half of the left. The ages ranged from eighteen months to fourteen years, and the sexes were about evenly distributed. About two-thirds of them were of the simple adult type, but the remainder combined with the hemiplegia a more or less advanced spastic paralysis of both legs. When the disease had lasted some time there was some bone shortening in addition to the muscular atrophy. One case showed a shortening of two inches in the length of the arm after a paralysis of seven years' standing, and three others showed a shortening of one inch. The muscular atrophy was comparatively slight, and nothing like so marked as in infantile spinal paralysis. The arm was in all cases affected more severely than the leg. Facial paralysis had been present in at least half the cases, and strabismus existed at the time of observation in more than half. Athetosis was noted in only two cases, but the intellect was so much affected that only six could be accounted of average intelligence, and seven were idiotic. Aphasia was present in four cases of left, and in three of right, hemiplegia. With a view to discovering the cause of the paralysis, the mothers were questioned as to the severity of the labor. In eight, the labor had been normal; in four, "very hard;" in seven, instruments were used—two of these still showing a depression in the skull on the side opposite the paralysis; and in the remainder no information could be obtained upon this point. Of the twelve cases of spastic paralysis mentioned later on, nine were born after an easy labor. Of the twenty-six hemiplegia cases, seven were noted immediately after birth, five in the first year, and twelve in the second year. One only followed upon any of the exanthemata—diphtheria. Sixteen of the sixty cases were the subjects of bilateral spastic paralysis, in addition to the seven described above, where it complicated hemiplegia. The ages ranged from two to twelve years. In eight it was noticed immediately after birth, in one of the others it ensued upon a fall of thirty-six feet, in two it followed upon "slow fever," and in the remainder no information was forthcoming. The intellect was very greatly affected, six being low-grade idiots, three very stupid, two backward and mischievous, and one apparently bright, though the mother said the child had "no sense;" in four cases the notes were defective. Seven were completely aphasic. Twelve were unable to walk—five of these having the cross-legged deformity due to spasm of the adductors. In seven, the hands were also impaired. Strabismus was noted nine times. Knee-jerk was increased in all, and ankle-clonus was elicited in a few. The palate was high in a small proportion of the cases. The remaining eighteen cases were not susceptible of much classification; nearly all were idiotic.—*The Boston Medical and Surgical Journal.*

The Contagion of Measles.—Dr. Ollivier states that it is wrong not to isolate children affected with measles before the eruption appears. The disease is contagious from the moment of onset, which is usually four or five days before the appearance of the eruption, and may be recognized by certain symptoms. If the little patients were isolated as soon as these symptoms are observed the chances of contagion would be considerably diminished. In all doubtful cases he advises isolation for a few days.

Antipyrin Rashes.—Dr. Claremont has described two cases of enteric fever treated by antipyrin, in which an exanthem due to the drug was observed. They are recorded in *The British Medical Journal*, of October 27, 1888. In the first case ten doses of fifteen grains had been given in the course of ten days when the eruption appeared. It came out simultaneously on the abdomen, thorax, back, and limbs, in the form of papules, darker, larger, and more solid than the spots of enteric fever. There was a considerable resemblance to measles. The eruption developed into enormous erythematous blotches, with much infiltration, their vivid red color being removed by pressure, leaving faint yellow pigmentary discoloration. The rash began to subside on the sixth day, and on the tenth day was only represented by faint coppery maculæ, resembling an old syphilitic eruption. Antipyrin was omitted on the appearance of the eruption. In the second case the drug had been given in 15-grain doses, generally twice a day, and omitted altogether for four days. The enteric exanthem had been unusually copious. On the twentieth day of the exhibition of the drug there was a papular erythematous rash on the extensor surfaces of the arms; this spread to the flexor surfaces, and also affected the calves. The antipyrin was omitted. On the fourth day the rash had almost gone, leaving only slight redness and desquamation. The patient had a relapse of fever, and was again treated with antipyrin without suffering from a return of the eruption. Dr. Claremont states that antipyrin rash generally is of the papulo-erythematous type, and begins on the extensor surfaces of the elbows and knees. It had been described in one case as commencing on the face, and in another as extending to the mucous membranes. Once vesicles had been present. Its most constant characters were its bilateral symmetry and its duration of about five days, irrespective of the continuance or withdrawal of the drug. The entire absence of subjective symptoms was exceptional. A scarlatiniform rash had been mentioned, but Dr. Claremont had been unable to ascertain that it was more than a transient flushing, such as is produced by belladonna.

Resorcin in the Treatment of Keloid.—Dr. Audeer has observed a case in which the application of resorcin was of great service in the treatment of keloid. The patient was a woman, whose right foot was curved over two-thirds of the dorsum, with an irregular star-shaped mass of scarry, raised tissue. It was very tender, so that walking was impeded. At night when in bed, and at changes of weather, the pain of the keloid was almost unbearable, so that at times the patient could not do her housework. A one-per-cent. ointment of resorcin was applied, and the foot bandaged. The patient was soon relieved, and the continued application of the treatment brought about a permanent cure of the pain.

Spontaneous Gangrene of Scrotum and Sheath of Penis.—Dr. Oltramare, of Geneva, describes a case of idiopathic sloughing (*gangrène foudroyante*) of the scrotum and sheath of the penis occurring in a merchant, aged thirty-seven. He was a robust man, enjoying excellent general health in spite of habitual alcoholic excesses. One evening, having imbibed a considerable quantity of spirits, the gentleman returned home with complaints about general lassitude, drowsiness, and severe lumbar pain. In the course of a sleepless night his attention was drawn to his penis, which was tumefied, hot, and tender. The next morning his wife discovered a brown violet patch on the dorsal aspect of the sheath of his penis. Forty-eight hours after the first symptoms, Dr. Oltramare found the man's penis greatly swollen, the scrotum being as large as a fœtal head; the gangrenous process of the penis' sheath reached backward nearly to the root, while the scrotal integuments were only highly congested and tender. The glans, urethra, and testicles were normal. On the third day of the disease there appeared a violet patch about the scrotal raphe, which in the course of the fourth and fifth days gradually spread over three-quarters of the scrotum. From the sixth day the dead portion of the integuments commenced to rapidly fall off in the shape of large flocks and strips, leaving a red, rough, suppurating, and easily-bleeding surface. It became now obvious that the sloughing process had been limited to the skin and subcutaneous cellular tissue. Cicatrization set in, and about the forty-fifth day the patient could go out.—*Revue Médicale de la Suisse Romaden.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 1, 1888.

THE CONTAGIOUSNESS OF PHTHISIS.

THE question of the contagiousness of pulmonary phthisis is one that has been debated for centuries, and even now is not regarded, by all whose opinions are worthy of consideration, as actually closed. The discovery of the tubercle bacillus, or sclerothrix, as Metschnikoff prefers to call it, and of its relation to the pathological processes of this disease, seemed to offer at once a solution of the problem, and to establish beyond question its contagiousness. Yet there are not wanting those who question the fact, notwithstanding. These say that the germs of the disease are floating everywhere in the atmosphere, and if the affection were contagious a much larger proportion of the population even than is now affected should be tuberculous. They instance, also, the commonly observed fact that the attendants and other patients in large hospitals, where many phthisical patients are collected together, seldom themselves contract the disease.

Those who hold to this view, however, overlook the fact, which is characteristic of contagious diseases, that a nation gradually acquires a certain degree of immunity, so that the individuals become less susceptible to the action of the organic poison, the soil, as it were, becoming exhausted from the too persistent cultivation without any rotation of the crops. It is among a new people, in a virgin soil, that the contagiousness of a disease is most apparent.

In a thoughtful paper on this subject, read before the Medical Society of the State of Pennsylvania in 1888, Dr. Lawrence F. Flick, of Philadelphia, dwells upon this very point and brings it forward as one of the arguments in support of the theory of the contagiousness of phthisis. The history of the disease in all new countries, he says, shows that it has in them a rise, a climax, and a decline in prevalency. In New York City the mortality from consumption fell from 1 in 4.2, in 1804, to 1 in 8.46 in 1859. A similar decline is seen in all the older localities in this country. Among the negroes the mortality was formerly very great, but it is now diminishing. Consumption was unknown among the American Indians prior to the settlement of the country by the white man, and for some time after it was a rare disease among them. But when it once obtained a foothold it spread very rapidly, as many as half the deaths among some tribes being attributed to it.

Another characteristic of contagious diseases, not without some exceptions, however, to which Dr. Flick refers, and which he says is very noticeable in phthisis, is that they will not tolerate the active presence of any other contagious disease. As regards comsumption, the author asserts that he has not been able to find a single authenticated case in which any contagious disease existed in a person suffering from well-marked and advanced phthisis. He made numerous inquiries concerning this point, and obtained negative replies in every case but one. This one was from Dr. Seaman, of the Riverside Hospital of this city, who wrote that he had seen deaths from small-pox, measles, scarlet fever, and diphtheria in persons suffering at the time from phthisis.

Still another fact adduced in support of the contagiousness of the disease is, that in many places which were formerly looked upon as health-resorts for consumptives, the disease is now prevalent so that they have lost their reputation and are even shunned. Dr. Flick mentions Santa Rosa, in California, as one of these places. In the early part of the eighteenth century even New York City was regarded as an excellent place of residence for those suffering from commencing phthisis, and the absence of the disease was attributed to the delightful climate. The author explains this deterioration of health-resorts by the influx of phthisical patients bringing the contagion with them.

Dr. Flick brings forward a number of additional arguments in support of this view, all of which are more or less weighty, but we cannot quote them here and must refer doubters of the theory to the original paper. It is a curious fact that the opposing theories concerning the contagiousness of the disease have had a geographical distribution in Europe for many years, the southern nations holding to the affirmative, while the northern ones, England especially, have vehemently denied this character.

THE URIC-ACID DIATHESIS.

SOME months ago Dr. Burney Yeo, in an article on the therapeutics of the uric-acid diathesis, drew up a table of the principal morbid conditions depending upon, or associated with, this condition. The table is so complete and conveniently arranged that we believe our readers will be glad to have it recorded for their convenience here.

Arthritic Affections.

Acute uritic arthritis (acute gout).

Chronic uritic arthritis	Anchyloses, Deformities. Uratic deposits (tophi).

Gastro-intestinal Affections.

Dysphagia from œsophageal spasm.

Dyspepsias...........	Cardialgia, or Gastrodynia (heartburn), Pyrosis, Enterodynia.

Circulatory Affections.

Palpitation of the heart and large vessels, irregular cardiac action, angina, chronic arteritis (aneurism), and phlebitis (embolism).

Respiratory Affections.

Laryngo-pharyngeal catarrh, bronchitis, asthma, and pleuritis (dry).

Renal and Urinary Affections.

Chronic interstitial nephritis.
"Primary renal gout" (uratic deposits in kidneys, and absence of arthritis).
Uratic gravel and calculi (renal and vesical), oxalate of lime.
Cystitis and irritable bladder.
Prostatitis.

Nerve Affections.

Neuralgias	Of various nerves, Lumbago, Sciatica.

Headaches (hemicrania), cramps of muscles, hysteria, and hypochondriasis, (epilepsy ?).

Organs of Sense.

Ophthalmia, conjunctivitis ("hot eye"), iritis, etc., and otitis (deafness).

Cutaneous Affections.

Eczema, psoriasis, prurigo (anal and vulvar), and acne.

PRINCIPAL PROPOSED REMEDIES FOR AFFECTIONS CONNECTED WITH THE URIC-ACID DIATHESIS.

Diet and Regimen Drugs.

Colchicum, salicylates, benzoates, guaiacum, iodide of potassium, arsenic, and sulphur.

Alkalies and Alkaline Earths.

Salts of potassium, sodium, lithium, ammonium, calcium, and magnesium.

Various Local Applications to Affected Joints.

Mineral Waters and Baths.	*a.* Alkaline (bicarb. of soda) for example, Vichy. *b.* Alkaline and aperient (carbonate and sulphate of soda), Carlsbad. *c.* Chloride of sodium, Wiesbaden, Homburg. *d.* Lime (earthy) waters, Contrexville, Bath. *e.* Indifferent (thermal), Buxton, Gastein. *f.* Sulphur, Harrowgate, Aix.

Water hot (and cold).

Dr. Yeo gives an interesting summary of the present views regarding the pathology of the uric-acid diathesis. Charcot and Murchison think that the liver is at fault, and that its function is disturbed so as to give rise to the production of uric acid in excess. Latham thinks it is a disorder of the constructive processes, on account of which glycocin is carried to the liver in excess, or is not acted on by the liver with sufficient vigor. The uric-acid diathesis is a muscular and hepatic constructive torpor, either or both. Ebstein thinks that uric acid is formed to excess in the muscles and bones. It is carried in the blood as a urate, here it irritates the capillaries, and causes local necroses about the joints. The necrosis develops an acid which precipitates the urates from the blood, forming the chalky deposits.

Frerichs and Wohler maintain that the formation of uric acid is an intermediate step in the transformation of albuminoid substances into urea, and that its accumulation in the blood is an indication of arrested oxidation in the progress of urea formation. This view has been hotly contested.

Beneke, Voit, and Lecorché assert, on the contrary, that the formation of urea and uric acid occurs in the organism quite independently of one another.

Bartels supports the theory of incomplete oxidation, and Bouchard asserts that in the uric-acid diathesis uric acid is not the chief factor, but is only thought to be so because we can see it! The diathesis in question is not a "uricæmia," but depends chiefly on the development of an excess of organic acids.

In the remarks made by Dr. Yeo on treatment, many practical hints are given, but there is no radical change from the ordinary views, as will be seen by the table.

English writers do not recognize yet the fact, observed by many American physicians, that in certain cases of the uric-acid diathesis a strongly nitrogenous diet is far more beneficial than the one ordinarily asserted to be indicated.

THE TREATMENT OF PULMONARY HEMORRHAGE.

PROBABLY the great majority of physicians, in cases of pulmonary hemorrhage, would put the patient to bed, apply ice to the chest, and administer ergot, morphine, quinine, turpentine, acetate of lead, or some vegetable astringent. Antipyrin has been recommended highly, and, being the vogue, would perhaps be tried.

Dr. Gustav Seiz (*Deut. Archiv. f. klin Med.*, Bd. xlii.) asserts that a larger proportion, at least, of these canonical measures are irrational and practically, in severe hemorrhage, quite useless. Ergot, as is well known, has theoretically no place in pulmonary hemorrhage, since the blood-vessels of the lungs have no vaso-motor nerves. The use of cold is said to be irrational also, because it cannot cause any reflex vascular spasm, while, by chilling the blood, it only lessens its power of coagulability.

Dr. Seiz advocates a return to the old Hippocratic method, revived by Traube, of ligaturing the extremities so as to stop the venous but not the arterial flow. Seiz found, by experimenting upon various persons, that there was a diminution in the intensity of the second pulmonary, and sometimes of the first pulmonary, sound after binding the extremities. His theory is that the heart, having a smaller amount of blood to manage, does not have to beat so hard; arterial and endocardiac pressures fall, the blood flows more slowly, and has a greater chance to coagulate. He found generally a fall in arterial pressure after the ligatures were put on. In two cases in which the method was applied it was very successful.

Though the method may be a good one, it seems a clumsy way to obtain arterial relaxation when we have drugs like aconite, veratrum, nitro-glycerine, and ipecac. Venesection, which is supposed to act by lowering blood-pressure, was strongly recommended by Graves and Trousseau.

THE HYDROGEN-GAS TEST.

VERY few medical or surgical procedures are perfect at the outset. They undergo gradual perfection through improved technique and a knowledge of their limitations. Not differing from this experience is likely to be the discovery of Dr. Senn. The latter's announcement in June last was positive, and seemed justified by his long series of careful experiments. He said, "in puncture or gunshot wounds of the gastro-intestinal canal, insufflation of hydrogen gas enables the surgeon to demonstrate positively the existence of the visceral injury without incurring the risks and medico-legal responsibilities incident to an explorative laparotomy."

As is always the case, the first results in the hands of others were confirmatory of the above assertion, and with some surgeons gas insufflation has become a recognized measure. Others are still sceptical, requiring further and more conclusive proof before giving adherence to the new theory and practice. The latter will read with interest the report of a case recently presented to, and discussed by, the St. Louis Medical and Surgical Society.

A Chinaman, aged twenty-five, was wounded in the stomach, while in a stooping posture, with a 38-calibre ball. The bullet entered between the fourth and fifth ribs, a little anterior to the left axillary line. The usual shock, pain, etc., were but slight. The fourth rib was resected about an inch in order to get at the wound, and the omentum was seen protruding through the diaphragm about two inches from the abdominal wall. There was considerable hemorrhage from the diaphragm, and considerable blood in the pleural cavity. A glass tube was inserted through the diaphragm. Care was taken that the omentum did not occlude the distal extremity. The insufflation of the gas gave negative results, and the conclusion was drawn that there was no injury to the alimentary canal. A speedy cessation of the hemorrhage took place. A rubber tube was passed through the diaphragm and the latter sewed tightly around it. The extremity of the tube passed out of the thoracic wound, which was treated with the usual antiseptic precautions.

The patient died twenty-six hours after the injury. The autopsy showed two holes in the stomach, about three or four inches from the cardia, a hole in the kidney, blood in the pelvic and abdominal cavities, and the bullet in the psoas muscle. The stomach contained a large quantity of food. When it was raised up none passed out. The operator thought that if his patient had been turned upon his side the gas would have escaped through the holes, and so given some positive indication as to the internal conditions. Eructations of gas during the insufflation proved that the alimentary canal was well inflated therewith.

The narration of this case is simply illustrative of the fact that we have very few diagnostic tests which are absolutely pathognomonic. Every procedure has its limitations, and what these are to be cannot easily be foretold. Clinical experience is the only safe guide. It is worthy of note that the surgeon in the case alluded to expressed his belief in the Senn method, notwithstanding its apparent failure in this instance.

CHLOROFORM OR ETHER ANÆSTHESIA.

WITH the present admitted tendency to use chloroform in place of ether as an anæsthetic, two articles on anæsthetics, by Dr. O. Kappeler (*Archiv f. klinischer Chirurg.*, Band 73, Hft. 2) and Dr. Buxton, will be read with interest. Dr. Kappeler's communication relates chiefly to the effects of ether and chloroform on the circulation. Dr. Kappeler finds that there is no fundamental difference between the action of chloroform, chloroform and morphia, methyl-bichloride, æthyl-chloride, hydrobromic ether, and dimethyl acetal. The æthyl-chloride ether (or A. C. E.) mixtures acts like ether at first, but, later and in smaller quantities, like chloroform. All the above-named mixtures have a decidedly different action on the circulation to ether.

Dr. Buxton's work includes a full discussion of the relative merits of chloroform and ether anæsthesia. Some of the well-known statistics on the subject are given. Of these a reviewer in the *Medical Chronicle* says:

"We know that between the years 1870 and 1885, 184 deaths have been published in England as occurring under chloroform, that is, slightly over twelve in the year. The number of times that chloroform has been administered in the same period is not known. At St. Bartholomew's, from 1875 to 1880, chloroform has been used 4,810 times with two deaths. Roger Williams has recorded as his personal experience 208 cases of chloroforming with one death. Between 1870 and 1885, 28 cases of death from ether have been recorded. St. Bartholomew's tables give 6,440 cases with two deaths, and Roger Williams' 1,050 cases with one death. Taking into account that chloroform is used in an infinitely larger number of cases in the United Kingdom than ether, and that it is nearly the only anæsthetic used out of the larger towns and hospitals, it will be admitted that 184 deaths from it, against 28 from ether, do not by any means show that it is the less safe of the two agents."

In one hospital in India it is said that 10,000 patients were chloroformed before a death occurred. A lower rate of mortality in chloroform anæsthesia appears to have been observed in the tropics.

Dr. Buxton points out that even admitting greater danger from chloroform, its use is indicated in the following circumstances:

a. In protracted operations about the mouth, jaws, nose, or pharynx, which necessitate the mouth and nose being uncovered.

b. All operations needing the employment of the actual cautery, or lighted candles, lamps, etc., in the vicinity of the mouth, ether being highly inflammable, and when mixed with air detonating, so that the incautious bringing of the apparatus near a light may lead to grave consequences.

c. Persons who are suffering from bronchitis, and those liable to that complaint; the emphysematous (if the condition be very pronounced) and, as a rule, asthmatics bear ether badly, since it creates cough and may clog the bronchial tubes with a quantity of excessive secretion.

d. In renal disease, when extensive, ether is said to induce suppression of urine, so that if given at all in these cases it should be with the utmost caution.

e. The vascular excitement to which ether gives rise contra-indicates its use for persons whose arteries are presumably brittle, etc.

f. In infants and very young children, etc.

g. As ether always provokes rapid breathing and not infrequently coughing, it should not be used when these are prejudicial to the patient, or to the success of the operation.

h. The presence of brain tumors, intestinal obstruction, and cancerous tumors is by some considered contra-indicatory of ether. (Wood.)

To these the *Chronicle* adds two other large groups of conditions:

1. All cases of brain surgery.

2. Where the circumstances of the patient or the requirements of the operation are such as to demand the securing of perfect rest by the free use of opiates, ether must be avoided on account of its action on the kidneys.

CLEVELAND NOT A MEDICAL CENTRE.—Our esteemed contemporary, the *Cleveland Medical Gazette*, announces the close of its third volume, and makes some comments, in a kindly but reproachful spirit, upon the lack of literary and scientific enthusiasm on the part of Cleveland physicians. In the past, some six or eight medical journals have been started in Cleveland, but died from want of support. The *Gazette* enjoys a measure of prosperity, but gets few contributions to its columns from local talent.

News of the Week.

Among the Extraordinary medico-legal cases that occasionally occur is one involving the question, "Can the flaccid penis be introduced by a woman into the vagina?" The question came before a court recently at Stargard, Prussia, a decrepid old man of eighty and his daughter being accused of incest. The court decided in the negative.

A Poem to Professor Esmarch.—The *New Yorker Medizinische Presse* publishes a poem in German, written by Dr. F. Lange, and read at the *Bier Zeitung*, which seems to have been a part of the entertainment tendered to Professor Esmarch by the *Deutsche Med. Gesellschaft*, on October 1st. The poem addressed to Professor Esmarch concludes with two verses which contain a tribute to the change in the bibulous habits of Brother Jonathan:

"'Es hält' sich Bruder Jonathan
Nicht allzuviel an Marzipan
Und kaltes 'Soda'-Wasser;
Statt 'Whiskey Sour' trinkt er Bier,
Damit er Phlegma acquirir',
Sonst wird er immer blasser.

"'Zum Schlusse sei ein 'Hoch' gebracht
Dem Manne deutscher Wissenschaft,
Den jede Sprache ehret;
Er lebe hoch! viel tausend Mal!
Darauf ergreif' ich den Pokal—
Darauf wird er geleert."

Are the Men Dying Out?—Professor Sanford E. Chaille has recently called attention to the well-known fact that the average life of woman is longer than that of man, and in most parts of the United States woman's expectation of life is greater. There is no immediate danger, however, of man dying out, for more males are born every year than females, while of late years the disparity between the expectation of life in women and men seems to be decreasing. For example, although Dr. Farr's and the older English insurance tables show figures that favor women, recent American tables (American Experience, thirty companies) are in favor of men in all but sixteen of the years from 10 to 99.

A Warning.—A stranger went to the house of a Brooklyn physician last week, just after the doctor had gone out, and told the latter's brother that he wanted to pay a bill of $20. The stranger gave a check for $35 and got a receipted bill and $15 in change. The check was a fraudulent one.

The Fifth Annual Medical Students' Missionary Conference was held in this city last week, Dr. D. B. St. J. Roosa presiding. Dr. Boudinot C. Atterbury, of Pekin, gave a very interesting account of the work done by the medical missionaries in China. They first opened a small house and hung over the door the imposing sign, "Everybody's healing place." At first none came. Then a few coolies took courage enough to venture within, and as they came out alive and felt better, they soon gave a basis for securing the confidence of others. The Chinese, he said, were extremely superstitious and suspicious, and commonly believe that the medical missionary mixes with his medicine something which will induce them to believe in Christianity. This was one of the greatest annoyances they had to contend with. Another annoyance was that the Chinaman did not like moderate treatment. He thought that if a small dose would cure a little of his pain, that a big dose all at once would settle it. He first found this fact out by learning of a Chinaman who had saved up powders that had been given him from time to time, and taken them all at once. They nearly killed him. There was an enormous field in China for the medical missionary, Dr. Atterbury said.

Yellow Fever.—One or two new cases are still reported daily at Jacksonville. The United States steamer Boston, from Hayti, arrived in this port last week with several cases of yellow fever on board. Among them, we regret to say, was that of the surgeon.

Protective Medical Insurance Associations.—The following case is of no little interest to physicians interested in checking the abuses of medical charity. A writ of mandamus has been issued in the case of the State *vs.* Insurance Commissioner Charles Shandrew, to compel him to record the certificate of the National Mutual Indemnity Association, a society to provide suitable medical and surgical attendance for its members in sickness or disability. Mr. Shandrew objects to register it, on the ground that experience has shown such associations to be radically defective. They not only fail to protect those for whose benefit they are incorporated, but afford facilities for the organization of insurance schemes, whose primary object is profit, regardless of the rights or interests of the members. Mr. Shandrew expects to make an example of the National Mutual Indemnity Association.—*Medical Standard.*

Quackery in Nebraska.—The *Omaha Clinic* says editorially: "Not more than three years ago a quack, void of all conscience, started out on his career in the North Platte Valley, equipped with recommendations from our best citizens as to his ability—fame does not say whether for cheating or curing the sick. Scarcely a year had elapsed, when a bright member of the Nebraska State Medical Society severed his connection therewith and followed in the footsteps of the quack. Happily, death shortened his career. Another member in another year had to be expelled from the society for the same disorder. And now comes a third, asking to be released from bondage, so that 'he may make good his battle among his compatriots with a moderate use of printer's ink.' Scarcely has this been read when a fourth member breaks loose from all restraint, not from ethical chains, but from all decency, by advertising as follows: 'Dr. ——, in a professional tour, will visit this city in the interest of his specialties, chronic diseases of the nervous system, heart, and blood, kidneys and bladder, organs of reproduction, organs of digestion, diseases of the skin, tumors, and the infirmities of old age, as elaborated at the Salpêtrière by the distinguished Professor T. M. Charcot,' etc."

Soteriology and the Stomach.—Under the head of "Soteriology," or the science of health, Dr. S. P. Crawford, Health Officer of Stockton, Cal., testifies to the importance of clean, well-cooked food as a preservative of health, even in the foulest air. As an illustration, he says (*Southern Practitioner*): "The Chinese race are a peculiar people, as free from disease as any other people, yet they live in an atmosphere so circumscribed and contaminated, that one unaccustomed to their quarters can scarcely breathe in them. I have often "run the gauntlet" of their asphyxiated atmospheres while inspecting their quarters as health officer. I account for their immunity from disease in such quarters, by their simplicity of diet, its exceptional cleanliness, and being thoroughly cooked. The meal for the whole family is cooked together in one pot; meat or meats, potatoes, vegetables, rice, all boiled and stirred together, and when thoroughly cooked, is ladled out in deep bowls and eaten with chop-sticks, which hold but a small quantity at a time, giving ample time for the mess to cool before it reaches the stomach. They drink no water, but use tea, either hot or cold, for drink, without milk or sugar. There is but little chance for microbes to breed between the boiling pot and their stomachs."

Malpractice Suit for Prescribing Antipyrine and Spirits of Nitrous Ether.—The *National Druggist* states that Dr. Castleman, a reputable physician of Houston, Tex., prescribed a mixture containing one and a half grain of antipyrine, and five or six minims of spirits of nitrous ether to the dose, for a child suffering from malarial congestion, the thermometer in the child's mouth registering 105° F. Shortly after taking the second dose the child went into convulsions, and in the course of eight or ten hours was dead. The parents of the child, instigated by a physician who had heard of the reputed toxicity of the combination of the two drugs, have brought suit against Dr. Castleman for malpractice. Two or three similar causes have been reported, which led Dr. Ludwig Bremer, of this city, to make an investigation as to the toxic effects of the compound formed by mixing antipyrine and sweet spirits of nitre. Dr. Bremer gave it as his opinion that the compound possessed no poisonous properties. The editor of the *National Druggist* tested the toxicity of the crystals, not only upon lower animals, but upon himself. His experience confirms the opinion rendered by Dr. Bremer.

A New Theory of Inflammation.—Professor Leber has succeeded in obtaining a chemical substance from cultivations of the *streptococcus pyogenes aureus*, to which he has given the name of phlogosine. This substance, from which all microbes have been carefully filtered, possesses the power of exciting inflammation to a remarkable degree. It is not an alkaloid, and does not contain nitrogen. It is quite distinct from the ptomaïnes which Brieger obtained from the same source, and which do not give rise to inflammation. Injected into the conjunctivæ, even in infinitesimal quantities, phlogosine sets up intense inflammation, followed by suppuration and necrosis. Dr. Leber concludes from his experiments that the substance attacks the leucocytes toward the point of inflammation in order that they may destroy, on the one hand, the pathogenic microbes, and on the other, the necrosed tissues.—*Medical Press.*

A Craze to Become Doctors.—The alarming news reaches us, *via* the *American Lancet*, that all medical colleges east and west, north and south, report enlargement of their classes, and that there seems to be an unusual craze on the part of young men everywhere, to enter the medical profession.

American Medical Association.—The fortieth annual meeting of this Association will be held at Newport, R. I., on Tuesday, June 25, 1889, instead of the *first* Tuesday in June, as appointed at the meeting in Cincinnati. The Address in Medicine will be given by Professor William Pepper, of Philadelphia; the Address in Surgery by Professor P. S. Connor, of Cincinnati; and the Address in State Medicine by Professor W. H. Welch, of Baltimore. The following constitute the Local Committee of Arrangements: H. R. Storer, Chairman; W. Thornton Parker, Secretary; C. F. Barker, M. E. Baldwin, C. A. Brackett, J. P. Curley, P. F. Curley, J. P. Donovan, H. Ecroyd, Jr., V. M. Francis, T. A. Kenefick, G. M. Odell, F. H. Rankin, W. C. Rives, Jr., S. H. Sears, W. S. Sherman, H. E. Turner. Associate Committee, appointed by the Rhode Island Medical Society, G. D. Hersey, W. H. Palmer, G. T. Swarts, all of Providence.

Chicken Cholera Microbes and the Rabbit Pest—Dr. Bancroft, of New South Wales, describes the preliminary experiments made to test Pasteur's method of destroying rabbits (*The Lancet*). The plan was to sprinkle the vegetables upon which the rabbits fed with a liquid containing the microbes of chicken cholera. All the rabbits so fed died, but the greater number of others not fed with the virus survived, notwithstanding that they were in contact for several days with the dead rabbits. In a further experiment, carried on in a larger enclosure provided with artificial burrows, all rabbits treated with chicken cholera died, with one exception—"a wild rabbit, which seems none the worse after having eaten three strong doses of the chicken-cholera cultivation." Hares are found to die, like rabbits, from chicken cholera—a disease, by the way, which has not yet appeared in Australian fowl-yards. In the experiments where artificial burrows were used there were some indications of contagion, one rabbit not fed on the virus having died of the disease; but Dr. Bancroft points out that sufficient time had not elapsed to say much of the contagious property, upon which, of course, would depend the value of the suggested method as an exterminating agent.

Cadaverin is a ptomaïne which has the power of producing suppuration without the presence of micro-organisms. Iodoform has been shown by Behring to destroy it, and hence, perhaps, its utility in surgery.

Competition in Medical Practice.—A Dr. Humphreys, of Camden Town, London, England, was committed for non-payment of debts. He explained that, though he had a practice in Camden Town, "he had so much opposition that he could scarcely get a living." The competition was so great, he said, "that some of the medical men attended patients for five cents per week!" The judge showed his belief in the doctor's plea by refusing to make an order.

Iodoform is said by Dr. Chauvin to be a valuable remedy in hæmoptysis. It is given in doses of two or three grains. As iodoform internally has probably only the effect of an iodide, the attributing a specific effect to the drug can hardly be correct. Besides, M. Chauvin usually adds tannin to his prescription.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 24, 1888.

W. P. NORTHRUP, M.D., PRESIDENT, IN THE CHAIR.

DR. T. MITCHELL PRUDDEN presented a uterus showing

EXTENSIVE LACERATION OF THE CERVIX.

The case was one of protracted labor with transverse presentation. Version was performed, but death resulted from septicæmia. The history was as follows:

"A woman thirty-five years of age, who had borne three children, and who had chronic phthisis involving both upper lobes, was in the eighth month of pregnancy, had been feeble and in bed for some time, and finally became delirious. This is all that could be learned of her previous history. On her admission to the hospital she was mildly delirious; had a temperature of 100° F.; was feeble; the urine was scanty, with fifteen per cent. albumin and granular casts. The fœtal heart-beats were heard, but there were no symptoms calling more detailed attention to her pregnant condition.

"On the day after admission she, for the first time, complained of abdominal pain. Examination revealed a transverse presentation with the hand and arm protruding from the cervix. On the introduction of the fingers for the performance of version, three or four ounces of a black grumous material came from the uterus. Version and delivery were performed without difficulty, no unusual force being used. There was no hemorrhage—the child was dead; an intra-uterine douche of bichloride of mercury, 1–3,000, was used. Two hours after delivery the temperature rose to 102° F.; but the woman appeared brighter and her general condition improved She was now passing not more than seven ounces of urine. On the following day her temperature was normal, and ranged from that to 101.5° F. Her pulse was better, but her general condition was worse. Under free stimulation she died, without further rise of temperature, about forty-eight hours after the delivery.

"*Autopsy.*—Brain and meninges, heart and spleen normal; lungs, chronic phthisis involving both upper lobes; liver, fatty; kidneys, small, rough, cortices thin and irregular; peritoneum normal, save that over the *cul-de-sac* of Douglas it was thickly bestrewn with small gray tubercles; uterus firmly contracted, its inner aspect posteriorly showing normal surface of placental attachment. The cervical portion was deeply and extensively lacerated, its surface rough and gangrenous. The uterine sinuses and both ovarian veins were filled with dense, firm thrombi. The right ovarian vein was so extremely distended with the thrombus—which was in part white, and apparently of considerable age—as to measure nearly five-eighths of an inch in diameter. The bladder was normal; the urethra presented on the lower side a small whitish patch of croupous exudate.

"This case seems to me to be of interest because it affords an excellent example of the rapid overwhelming of the system with poisonous material from an injured surface, without the occurrence of any well-defined inflammatory lesion. How long in this case the labor may have been going on before its discovery is only a matter of conjecture, but it seems most likely that the laceration, and very probably the infection, had occurred before the admission of the patient to the hospital.

"I think that it is convenient, in the present state of our knowledge—although we have perhaps no strict scientific reasons for doing so—to group

THE PUERPERAL INFECTIONS

into two classes, one which we may call the *putrid infection*—perhaps most often caused by the putrefaction of retained placental fragments, or, as in our case, by gangrene following a more or less extensive injury; and that which is well enough termed *purulent infection* or puerperal pyæmia, in which there are somewhere foci of suppurative inflammation. The latter form of puerperal infection would be that which more strictly comes under the heading of puerperal fever.

"I have taken the liberty of calling attention to this grouping of these puerperal conditions, simply to emphasize that class of which this is so excellent an example, in which women die after delivery, and sometimes very soon after, without much rise of temperature, and without the existence of any appreciable inflammatory lesions. They not only die, but seem often to do so to the great surprise of the attending physician, who is prone to call upon the pathologist for the discovery of a cause for death. And this cause the pathologist has frequently to discover or to postulate without the aid of any well-defined anatomical data. It is perhaps only the bacteriologist who has seen much of the effects of pathogenic bacteria on animals, who is ready to give an unquestioning acquiescence to a "cause of death" which leaves as little trace of its modus operandi as does in many cases puerperal septicæmia."

DR. GEORGE C. FREEBORN presented a specimen of

EPITHELIOMA OF THE BODY OF THE UTERUS.

The patient, aged fifty-six years, has been married forty years. Two years ago she noticed a scanty discharge from the uterus; this increased, became watery in character, sometimes bloody, and finally muco-purulent. She had complained of but little pain. The uterus was removed by hysterectomy.

The uterus measured 12 ctm. in length and 8 ctm. across the horns. The body was rather globular in form. On opening the uterus, an irregular roundish mass, measuring 6 × 5 ctm., was found growing from the posterior wall of the body. It projected about $1\frac{1}{2}$ ctm. above the mucous membrane. The surface was soft, white in color, and had a "cauliflower" appearance. Microscopical examination showed the growth to be epithelioma.

Dr. Freeborn also presented a second specimen, showing

RUPTURE OF THE COLON FOLLOWING OVARIOTOMY.

The patient was operated on October 1st, both ovaries being removed, they being cystic. Several adhesions to the intestines were found with the left ovary, and were broken up. After breaking up a rather firm one, severe hemorrhage followed; the bleeding point was found and ligated, and the operation finished in the usual manner.

On October 4th symptoms of rupture of the intestine occurred. Owing to the weak condition of the patient, exploratory laparotomy was not deemed advisable. General peritonitis set in, and the patient died October 24th.

Post-mortem examination showed general purulent peritonitis, the abdominal cavity being filled with pus, and solid and liquid fæces. In the upper and left portion of the sigmoid flexure of the colon, an oval opening 2 inches long and $\frac{1}{2}$ inch broad was found, the whole of the intestinal walls included in the above dimensions having sloughed away. At the upper end of the opening a silk ligature was found imbedded in the tissue. The rectum was very much contracted, probably from the want of use, as all fæcal matter had been discharged through the drainage-tube from the time of the symptoms of rupture.

The point of interest in this case is whether, in breaking up of the adhesion, the peritoneal and muscular coat was torn away, leaving only the mucous membrane. If this were the case, the latter, being deprived of its means of nourishment, would have sloughed, and thus caused the opening.

DR. H. M. BIGGS presented a series of specimens illustrating various forms of

DISEASE OF THE VERMIFORM APPENDIX.

The first specimen was accompanied by no clinical history, as the patient had died two or three hours after admission to the hospital. At the autopsy a general peritonitis was found. There was a perforation of the vermiform appendix, and a fæcal concretion was discovered in the abdominal cavity.

The second specimen was taken from the body of a patient suffering from typhoid fever, who had died with the usual symptoms of intestinal perforation. The autopsy revealed ulceration and perforation of both the ileum and vermiform. The ulceration in the latter was ragged and did not have the appearance of a typhoid lesion. If it were a typhoid ulcer, however, it would be a rather curious coincidence to have perforation of both the ileum and vermiform appendix.

The third specimen was one of

TUBERCULOSIS OF THE VERMIFORM APPENDIX.

About an inch of the extremity of the process was cut off from the remainder and was filled with a cheesy material. There was tubercular ulceration also in the ileum, but here there were no tubercles on the peritoneal surface of the gut, so that external inspection of the bowel would not have led the examiner to suspect tubercular ulceration.

Dr. Biggs then reported another case, of which the specimen was not shown, of impaction of fæcal matter in the appendix. The body was the size of the end of the little finger, and was situated at some distance from the opening. The opening was very much smaller than the fæcal mass, so that the latter must have been formed within the appendix, and could not have passed into it from the cæcum. These cases of vermiform perforation seem to be growing quite common, the speaker said; he had seen ten or twelve cases within the last two years.

Dr. Biggs then presented another specimen showing

MULTIPLE DIVERTICULA OF THE LARGE INTESTINE.

The pouches were small but quite numerous.

The last specimen was one of

RUPTURE OF THE UTERUS

occurring in a case of criminal abortion. The organ had been removed from the body of a girl sixteen years of age. The abortion had been produced at the third month of pregnancy. On the anterior wall of the uterus were to be seen several punctures, possibly made by a knitting-needle or a straightened hair-pin. In the lateral wall was a large laceration, an inch and an half in length, which had evidently been made by a different instrument, and probably at a later period than had been the smaller punctures. The cervix was bruised, but was not involved in the laceration of the body of the organ.

Dr. Mendelson, referring to the specimens of vermiform disease, asked how much importance, in Dr. Biggs' opinion, was to be attached to the popular belief that the seeds of fruit were a cause of vermiform disease. Considering the great quantities of grape-seeds that are swallowed at this season, and the comparatively few cases of disease of the vermiform appendix, it hardly seems that the swallowing of seeds can be a very efficient cause.

Dr. Biggs said that he had never found any foreign bodies in the appendix other than fecal accumulations. He had, however, sometimes found other substances forming the nucleus around which the fecal matter had accumulated. He remembered one case in which the nucleus seemed to be a raisin stem. He did not believe that seeds had any influence in the production of vermiform disease.

Dr. John C. Peters said that one of the earliest specimens presented to the Society was brought by Dr. Alonzo Clark, in which there were several layers of strawberry-seeds in the vermiform appendix; these seemed to have been accumulating for several years, to judge from the appearance of the different layers. That they were really seeds, and not fecal accumulations resembling seeds, was proved by microscopical examination.

Dr. Prudden said that whether the seeds merely formed the nucleus, or were the whole accumulation, their presence was significant, and he asked Dr. Biggs whether he had often found foreign bodies as nuclei.

Dr. Biggs said that in the majority of cases that he had seen there were no seeds or other foreign bodies except fecal concretions. Out of a dozen or more cases that he had seen, however, during the past two years, there was but one in which a rupture of the vermiform had occurred, and no fecal concretion had been found in the abdominal cavity—aside from the one of ulceration complicating typhoid lesions in the ileum, which he had just reported. He believed that cases of simple necrotic ulceration of the vermiform appendix were not common, if they occurred at all.

Dr. B. F. Curtis referred to a case under the care of Dr. Abbe, in St. Luke's Hospital, in which a pin was found in the abdominal cavity. The case had been operated upon some months before and a sinus had remained. The pin was found at the second operation.

Dr. Prudden said that he had searched for seeds in all the cases which had come under his observation, but he had never yet succeeded in finding any. He had seen some bodies which looked like seeds, but examination had always shown that they were not seeds, but simple concretions.

Dr. L. E. Holt had seen the case referred to by Dr. Curtis, at the time of the first operation, and he was quite positive that no pin was present at that time. As to the case of intestinal tuberculosis, he had also seen one in which there were no evidences of tuberculosis upon the peritoneal surface of the bowel.

Dr. Thacher said that he had recently made an autopsy in which he had found multiple diverticula of the intestine similar to those in the specimen shown by Dr. Biggs.

Dr. Mendelson recalled the case reported to the Society several months ago by Dr. Ferguson. He was present at the autopsy. A diagnosis had been made of abscess of the liver. The cause of the abscess was not evident at first, but it was traced at the autopsy. There was found in the mesentery, behind the descending colon, an abscess which, extending upward, involved the tail of the pancreas. In consequence, thrombosis of the pancreatic veins had occurred, the thrombotic process extending into the liver, and causing multiple abscesses there. The origin of the abscess behind the colon was not at first apparent, but on dissecting out the colon carefully, it was found to have many large and small diverticula, one of which having ulcerated, had given rise to all the trouble.

Dr. Biggs related a case of diverticulum of the ileum, in which a pin was found imbedded in the mucous membrane.

The President asked Dr. Biggs what was the nature of the instrument used in the case of criminal abortion reported by him.

Dr. Biggs replied that there had evidently been two instruments employed, for the punctures in the anterior wall were made probably by a knitting-needle or a straightened hair-pin. The lacerations in the lateral wall must have been caused by the use of a much larger and coarser tool. It was probable also, that the injuries had been inflicted at two different times, and that the first and more simple instrument having failed, more active measures were undertaken.

Dr. L. Emmett Holt presented the lungs of a child two years of age, showing

PRIMARY CROUPOUS PNEUMONIA, COMPLICATED BY PURULENT PLEURISY, AND TERMINATING IN GANGRENE.

Female child, aged two years, an inmate of the New York Infant Asylum. Stout and well until twelve days before death, when she was taken suddenly ill, with a temperature of 102° F., which rose the same evening to 104°. From that time it continued steadily high, ranging between 103° and 105.5° F., on two occasions reaching 106°. It fell only once as low as 101.5°, on the day before death. With the temperature there were present all the usual symptoms of lobar pneumonia, and by the fourth day the physical signs revealed complete consolidation of the right upper lobe. On the sixth day friction-sounds were heard over this lobe, and the signs indicated an extension of the consolidation into the middle lobe in front and lower lobe behind. Up to this time there had been but little prostration. During the next two days there developed a marked change for the worse. The prostration was so great that the child was not disturbed for any further examination of the chest. In spite of very free stimulation she lost ground steadily, and died of exhaustion on the twelfth day. There were no cerebral symptoms present at any time.

Autopsy.—The brain was normal. The right chest contained six ounces of pus which was not fetid. This was contained in two cavities; the larger one embraced nearly the whole pleural cavity, and the smaller one was just beneath the sternum and contained only half an ounce. The visceral and parietal layers of the pleura were covered with a thick, shaggy layer of fibrin and pus.

The right lower lobe was compressed, but was otherwise normal. The whole upper lobe and the upper half of the middle lobe were hepatized, of a brownish-red color. On section there were seen in the upper lobe three or four gangrenous areas in the centre of the lobe, the largest being about three-fourths of an inch in diameter; they were broken down in the centre. The gangrenous odor was scarcely perceptible. The largest artery leading to this region of lung was plugged by a thrombus, white, firm, and adherent, and to all appearance ante-mortem in its formation. In the lower border of the upper lobe another wedge-shaped gangrenous spot existed, extending to the surface of the lung. A similar thrombus was found in a vessel here.

The left lung was somewhat emphysematous above, and congested below; there were a few minute spots of broncho-pneumonia in the posterior border of the upper lobe; otherwise this lung was normal.

The heart, pericardium, stomach, intestines, and spleen were normal. The liver was large and pale. The kidneys were one and one-half time the normal size, the cortex was pale and thickened, and there was the general appearance of quite a well-marked parenchymatous nephritis.

A microscopical examination made from the hepatized lung showed the exudation to be almost entirely fibrinous, only a few small round cells and epithelial cells being seen in the alveoli.

DR. PRUDDEN said that, in the course of the examination with Dr. Northrup of a large number of cases of broncho-pneumonia in children, he had seen four cases, all in children not over three years of age, of genuine acute lobar pneumonia with extensive pleurisy. The gross and microscopical appearances of these lungs corresponded with those of acute lobar pneumonia. The question of these cases being genuine acute lobar pneumonia, similar to that so common in adults, was settled by the results of culture, which showed in all the cases the pneumococcus of Fraenkel in large numbers.

THE PRESIDENT said that these four cases were only four cases out of a very large number, and that they were not cited as evidence of the comparative frequency of the disease in children, but of its rarity.

DR. THACHER asked what these lungs looked like to the naked eye.

THE PRESIDENT replied that they presented much the same appearance as the lungs of adults who had died from croupous pneumonia.

DR. VAN GIESON presented some sections of the spinal cord from a case of compression myelitis, showing

DEGENERATION OF THE ANTERO LATERAL ASCENDING COLUMN.

After hardening in Müller's fluid, a portion of the upper dorsal region, two and a half centimetres in length, was seen to be transversely flattened, the entirety of the gray matter was absent, and a considerable portion of the cord was softened. Above the softened portion the posterior median and direct cerebellar columns were lighter in color than the surrounding white matter. There was also a bilateral narrow, light-colored zone in the periphery, continuous with, and anterior to, the direct cerebellar column. Following the periphery of the cord, it extended forward to a point about opposite the middle of the anterior horn. Below the softened portion there were bilateral light-colored areas corresponding to the direct and crossed pyramidal tracts.

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN SURGERY.

Stated Meeting, November 12, 1888.

ROBERT ABBE, M.D., IN THE CHAIR.

ENORMOUS TUMOR OF THE ARM AT THE SEAT OF AN OLD FRACTURE.

DR. G. B. PHELPS presented an aged man who, forty years ago, had fallen three stories and injured the arm. He was taken to what he called Quarantine, and when seen by a doctor was told that his arm was broken, but that so long a time had elapsed it was then too late to do anything for it. He remained in the place about eighteen weeks, and since then had been able to do ordinary day labor, but could not throw dirt out of a trench. The coracoid process of the scapula was very prominent, the deltoid was atrophied; an immense tumor projected from the posterior surface of the arm, which the patient said had been increasing in size for years. The joints were free, there was no pain, no disturbance of the circulation.

THE CHAIRMAN thought it was an outgrowth from the humerus, perhaps with a narrow neck, but spreading out beneath the muscles upward and downward.

SUPRA-ACROMIAL DISLOCATION OF THE CLAVICLE.

DR. CHARLES A. POWERS presented the man, the case being an interesting one on account of the marked deformity after the accident, and the excellent results obtained by a splint of adhesive plaster, one strip passing beneath the elbow, up the inner aspect of the arm, over and back of the shoulder, and the other passing from under the elbow, up the outer aspect of the arm, over to the front of the shoulder, the two elevating the arm and pressing down on the clavicle. A pad was placed in the axilla, and the arm was bound to the chest.

DR. JAMES P. TUTTLE had employed a similar splint in a case of dislocation of the outer end of the clavicle four years ago, with nearly as good results.

DRAINAGE IN CEREBRAL SURGERY.

DR. POWERS also presented a man who, about eighteen months ago, had been trephined by Dr. Weir over the motor area for the left arm. This arm was paralyzed and there was aphasia. A blood-clot was found, which, when removed, left a large cavity which would not drain. At the suggestion of Dr. Weir, Dr. Powers made a counter-opening four inches backward and downward, for drainage. Unfortunately a good deal of periosteum was removed from surrounding bone, which necrosed to the extent of about a silver dollar. The wound was for a time dressed antiseptically, but afterward the man acted as a porter and the dura mater was protected only by sticking-plaster, yet this exposure of the membrane to germs did not result in infection.

It was the speaker's belief that to Dr. Weir was due the honor of having first suggested counter-opening for drainage in cerebral cases, although Dr. Nancrede in an article this year made the statement that this had become a recognized surgical procedure. There had been no bone-plantation in this case. The patient showed no mental disturbance.

TETANUS HYDROPHOBICUS.

Dr. G. B. Phelps read the paper, which included the history of a case, that of a boy, aged sixteen, who, on November 16, 1886, applied for treatment at the out-patient department of Chambers Street Hospital for a wound inflicted over the left eyebrow by a stone thrown at him by another boy. The bone was exposed, but there was no fracture. The wound was irrigated with a solution of carbolic acid, and a dressing applied. Two days later Dr. Phelps saw the patient, when the wound was painful to pressure, swollen, the edges adherent. A cold-water compress was applied, to be kept wet. Eight days after the injury the reddened and swollen condition had disappeared, and a perfectly healthy appearence was present, but the patient had left facial paralysis, and had complained of difficulty in opening the mouth since the day before. The paralysis was on the same side as the wound. The patient was sent to Dr. Amidon, who made a careful examination. On the ninth day the paralysis was more marked, and there was still painful spasm of the left masseter muscle. On the eleventh day he was up and about at his home. There was occasional spasm of the temporal and masseter muscles, he could swallow well, but attempts at examination of the palate caused marked spasm of the muscles of the jaw. Bromides were administered. On the twelfth day the jaws were firmly set, the patient could hardly speak, the face was drawn to the right; he was restless, pulse and temperature normal, respiration 36. He was given liquid food. Bromide of potassium, 360 grains, was administered in twenty-four hours, also 160 grains of chloral hydrate. On the fifteenth day the patient, having in the meantime grown weaker, was unable to take anything by the mouth. Any attempt to swallow caused violent spasm of the muscles of deglutition. He died later in the day. The autopsy showed œdema of the lungs.

The case seemed to be a typical one of head tetanus, or tetanus hydrophobicus; it was typical because the paralysis and the trismus were on the same side as the lesion, and the muscles of deglutition were involved.

Of this disease, which was first described in 1870, he had collected 25 cases—20 males and 5 females; the ages varied from 2½ to 59 years. In 22 the paralysis was on the same side as the injury; in 2 on the opposite side; in 1, the injury being on the root of the nose, there was paralysis on both sides; in 10 cases trismus and paralysis developed at the same time, on the average the eighth day after the receipt of the wound; in 11 cases the trismus developed first; in 1 case the trismus developed within twenty-four hours; in 1 not until the fourteenth day after the wound. The percentage of deaths was 68. The average duration of the symptoms was thirty-eight days. Large doses of chloral hydrate seemed to do most good. In 12 cases an autopsy was held, and in some a microscopical examination of the seventh nerve was made, but no cause for the paralysis was found. The wound was the result of an operation in but one case. It had been suggested that the infectious matter came from the horse. This could have been possible from the manner of infliction of the wound in a number of these cases. In 5 cases the symptoms developed after the wound had fully healed; in some, before any reparative process had set in. Various theories had been offered in explanation. The cases were very rare.

Dr. B. F. Curtis had seen this patient, and remarked that his appearance was striking, with the paralysis of the left side of the face, the escape of saliva from the corner of the mouth, the spasm of the muscles of the face and extending down the shoulder and arm on that side. Attempts were made to separate the teeth, but resulted in so great spasm and pain that they desisted. He asked whether the interference with swallowing was shown to be due to paralysis, or whether to spasm of the muscles of deglutition.

Dr. Phelps thought that in this case it was due to spasm, and spasm had been proven to be the cause in one of the cases on record, since an attempt to pass a stomach-tube through the nose was resisted by spasm of the muscles below.

Dr. R. W. Amidon saw Dr. Phelps' case twice. Probably all were pretty well convinced that tetanus is a septic disease, probably arising from a parasite the exact nature of which was not known. The question for discussion should be, he thought, why in these cases the tetanic symptoms were so extraordinarily localized and limited. Why should the symptoms be confined to the head, and why was there facial paralysis, which was not common in ordinary tetanus? The distinctive features of this form of tetanus he understood to be facial paralysis on the same same side as the lesion, which latter was also in the face. But in one case which was treated at the New York Hospital, and which was not included in Dr. Phelps' list, the injury was on the shoulder. Therefore the question of the location of the lesion could be set aside. But Dr. Phelps had also two cases on his list in which the paralysis of the face was on the opposite side from the injury, which fact precluded another apparent characteristic. He had been unable to disassociate tetanus and hydrophobia. It seemed the only difference between them was that in tetanus the tetanic symptoms, the result of an apparently specific poison, became manifest a good deal sooner than hydrophobic symptoms. In hydrophobia the symptoms pointed to lesion about the nucleus of origin of the hypoglossal nerve and spinal accessory, while in tetanus other nerve-origins were implicated as well, as shown by the facial paralysis and opisthotonus. The symptoms in tetanus hydrophobicus became before death more or less general, the patient dying in general convulsions.

It was some years since he had studied the lesions in a case of tetanus in a girl. There were lesions of septicæmia in various organs, and he felt convinced that those in the medulla oblongata and upper portion of the cord fully explained the symptoms from which the patient had suffered. There were signs of vascular irritation and some hemorrhagic spots about the roots of the spinal accessory, the glosso-pharyngeal, the hypoglossal nerves, and evidence of ante-mortem softening in areas from the size of a pin to that of a pea in the medulla. These areas of softening were in the neighborhood of the fifth nerve, particularly of its motor nucleus, and would explain the trismus and secondary paralysis of corresponding muscles.

Dr. C. A. Powers mentioned a case of tetanus brought to the hospital a year ago last September, that of a boy who was in a state of marked opisthotonus. No wound could be found except a small scab beneath one great toe. The house-surgeon, Dr. Dench, gave about nine hundred and sixty grains of bromide in two days, and continued their use afterward according to indications. The patient recovered within three or four weeks.

The Chairman thought the conclusion was evident that the type of tetanus, the subject of the paper, was not essentially different from ordinary tetanus or that arising from wounds in any portion of the body.

Dr. W. K. Otis read a paper on

RECENT IMPROVEMENTS IN ENDOSCOPIC APPARATUS.

The first practical use of the endoscope was made by Desormeaux in 1853. His instrument, which was essentially the one much used to-day, had marked disadvantages. In 1879 Nitzer employed the electric light, but the apparatus was too cumbersome. Leiter's electric light, introduced in 1887, was small, light, inexpensive, and gave an illumination by the reflector as good as could be desired.

Dr. Otis detached the tube from the light, for the least movement of the latter caused sufficient movement at the end of the tube sometimes to give rise to pain. His attention had first been directed to improving the obturator. In order to introduce the tube without causing pain and, if possible, to avoid any bleeding, he employed an obturator the end of which was soft rubber. This, being slightly larger than the endoscopic tube, spread out over its edges and prevented irritation. After introduction, the rod attached to the rubber was pulled upon, elongating the rubber so that it could be withdrawn through the endoscopic tube.

In order to avoid constant swabbing, especially when bleeding was present, he placed a tube about the size of a knitting needle along the inside of the endoscopic tube to within an eighth of an inch of its lower end, piercing it at the upper end at right angles. This end was covered with a small rubber bulb, pressure on which expelled the air, and relaxation caused it to suck up the remains of the blood or water, after flooding the endoscopic tube. By attaching a hypodermic syringe any medicament could be injected.

With the straight tube one could get a view down the angle of the urethra. Dr. Otis exhibited one with a bend near its lower end, and, by the aid of a small mirror introduced down the tube, obtained a view beyond the bend in the urethra. The endoscope had proved of less value in diseases of the urethra than many had anticipated. He did not think the numerous divisions of urethritis made by the Germans were practical.

Dr. F. R. Sturgis preferred kerosene light to the electric light in endoscopic examinations of the urethra. The electric instrument made too distinct markings between light and shade, giving the appearance of a pathological condition where none existed. The four-inch tube was long enough and gave the best view. He preferred that made of silver. He also thought the value of the urethroscope had been overestimated, and that the division of urethritis into many forms by the Germans was fallacious. The instrument had been of value to him in making applications of nitrate of silver directly to the affected parts in certain conditions.

Dr. J. P. Tuttle had discarded the silver tube for the rubber, and employed the gas argand-burner. He had seen two cases of urethritis membranosa, the existence of which variety Dr. Sturgis had doubted.

Dr. W. K. Otis closed the discussion, and said he had not found the objection to the electric light mentioned by Dr. Sturgis.

Dr. George E. Brewer then read a paper (see p. 643) on

A CASE OF CONGENITAL ABSENCE OF THE ENTIRE RECTUM; ARTIFICIAL ANUS BY LUMBO-COLOTOMY.

Dr. T. J. Kearney recited a case of imperforate anus which he saw in 1883. There was no sign of an anus, no depression suggesting the presence of the rectum in the perineal region. The parents rejected lumbo-colotomy. The child died about the fifth day. Its body had a somewhat jaundiced hue, and spots pointing seemingly to commencing decomposition were present on the abdomen.

The Chairman had operated a few weeks ago for imperforate anus, cutting about half an inch to reach the rectum. A free evacuation of meconium took place, but the child died. This patient also had a jaundiced hue.

Dr. B. F. Curtis had recently read, in a French medical journal, the case of a woman who was found to be without an anus in the normal situation, and passed her fæces through an opening in the vaginal wall which had complete sphincter control even when the passages were thin.

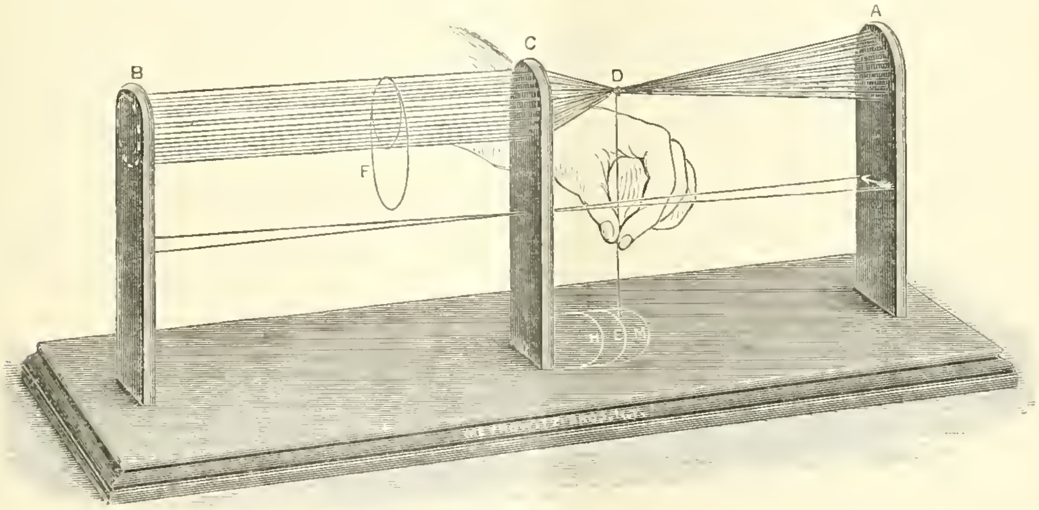
New Instruments.

A NEW INSTRUMENT FOR DEMONSTRATING REFRACTION.

By S. M. Payne, M.D.,

INSTRUCTOR IN OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC, CLINICAL ASSISTANT TO THE MANHATTAN EYE AND EAR HOSPITAL, NEW YORK.

The annexed is a cut of an instrument which I have devised for teaching refraction. It consists of a base and three upright pieces. In the top of each upright is a circle of small holes through which threads are passed representing a cylinder. The three uprights are named *A*, *C*, and *B*—*C* representing the cornea. On the base are represented an emmetropic, hypermetropic, and myopic eye, marked *E*, *H*, and *M*. On one side of the cornea the cylinder of rays is brought to a focus over *E* by drawing the string *D*, showing the emmetropic eye. As parallel rays will not focus on the retina of any but an emmetropic eye, the string *F* is slightly drawn near *C*, to make the rays diverge, and the string *D* is drawn to a focus over *M*. This represents the myopic eye. To represent the hypermetropic eye, a disk larger than the cylinder is placed in it near *C*, causing the rays to converge toward *C*, and the string drawn to a focus over *H*.



To show that when the focus is on *M* the rays converge from *C* to some given point, the string *F* is drawn to a focus near the disk *B*. This also shows the act of accommodation when the focus is held at *H* or *E*. To show astigmatism the string *D* is drawn nearly to a focus and then two fingers press it together in one meridian, showing that the opposite meridian does not focus at that point.

Between the base and cylinder are two threads, one passing from each side of upright *A* to the opposite side of *B*, crossing each other in a hole in the centre of *C*. This shows the comparative size of the inverted image on the retina of a hypermetropic, emmetropic, or myopic eye, showing that the image enlarges with the lengthening of the eye.

This instrument is manufactured and sold by Meyrowitz Brothers, 295 and 297 Fourth Avenue, New York.

266 Madison Avenue.

A NEW URETHROTOME FOR CLOSE STRICTURES OF THE PENILE URETHRA.

By JOHN BLAKE WHITE, M.D.,
PHYSICIAN TO CHARITY HOSPITAL, CONSULTING PHYSICIAN TO HOUSE OF REFUGE, NEW YORK.

Internal urethrotomy is practised in comparatively so large a proportion of cases of stricture, and the means by which the purpose is effected are often so very unsatisfactory, that any offer to improve the same must interest all surgeons.

Among the instruments devised to effect relief in cases of very narrow urethral calibre, none have yet taken precedence of the deft stricture-cutter of Maisonneuve. With all its perfections, nevertheless, this instrument fails to meet the stern requirements of many cases, proving, not infrequently, a hazardous weapon in the hands of many a cautious operator.

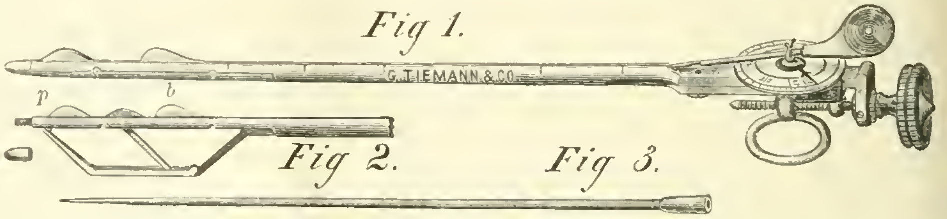


Fig 1.
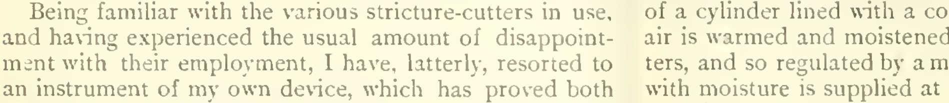
Fig 2.
Fig 3.

In order to liberate a stricture with this instrument, the blade is urged, with a steady and determined hand, toward the obstruction. By such manœuvre a fold of adjacent healthy structure is likely to be pushed up before the blade, and is, of course, incised together with the morbid tissue. This necessarily complicates the operation by endangering hemorrhage, and exposes, needlessly, a long line of denuded surface to heal by the usual process of cicatrization, which occasions narrowing of the urethra after the operation, and sometimes curvature of the penis follows.

For the reasons stated, therefore, I think all operators will agree with me that an instrument contrived to cut a stricture from behind forward, similarly to the admirable dilating urethrotome of Dr. F. N. Otis, which is only applicable to strictures of large calibre, would be far preferable for operations in strictures of very small calibre.

Being familiar with the various stricture-cutters in use, and having experienced the usual amount of disappointment with their employment, I have, latterly, resorted to an instrument of my own device, which has proved both safe and effectual in my hands, and, furthermore, so devoid of ordinary exceptions that I lay it before the profession with pleasure.

My first experience with this instrument was with a case, in my service at Charity Hospital, of such exceeding narrow urethral calibre that a No. 3 F. bougie could with difficulty be passed. The instrument has a much smaller staff than the ordinary one of Maisonneuve, and is made to cut from behind the stricture forward.



The above instrument consists of two cannulæ, one fitting easily within the other. The distal end of the larger (or outer) cannula is furnished with a bulb, *b*. The smaller (or inner) cannula carries a filiform bougie, *r*, and a grooved prominence, *p*, which acts as a sheath for a blade, *m*. The blade is attached to a delicate rod, made small enough to play freely through the calibre of the smaller cannula, and, by manipulation at *c*, can be made to traverse back and forth between the bulb *b* and the sheath *p*. At *d* is a graduated scale, which serves both to indicate the amount of stricture-tissue involved and to regulate the distance the knife is to be withdrawn, in order to avoid the unnecessary incision of non-morbid tissue.

For strictures of large calibre I have been in the habit of using the following instrument, modelled after the admirable dilating urethrotome of Dr. Otis, which I believe possesses additional very useful modifications.

A filiform bougie is attached to the distal end, as in the other instrument already described, and serves to direct the bulb *p* past the stricture, at which point firm pressure is sometimes necessary, and may be safely exerted. Without the bougie a false passage might easily be made. The stricture-tissue is firmly held between *p* and *b*, by dilating the extremity of the instrument to the required calibre, when the knife is to be drawn forward from *p* to *b* and returned again to *p*, thus severing completely the stricture-tissue without wounding the adjacent sound mucous membrane.

No hemorrhage of moment has yet followed the use of this urethrotome, and the reason is very manifest, viz., the incision is made solely through morbid tissue, and is much less extensive than that which is ordinarily made in performing internal urethrotomy. After the urethrotome is removed, it is my habit to wash out the urethra with the bichloride solution (1 in 20,000) and introduce a full-sized sound, at least beyond the point of incision.

It will be observed that by the above methods of operating the greatest degree of accuracy of incision is attained, and that there is the minimum degree of risk run in wounding normal parts of the urethral canal.

Hot Moist Inhalations in Phthisis.—Dr. Eduard Krull, of Güstrow, in Mecklenburg, in a contribution to the *Berliner Klinische Wochenschrift* (Nos. 39 and 40), describes a new method of giving inhalations, employed by himself in cases of phthisis. The apparatus consists of a cylinder lined with a coiling steam-pipe, in which the air is warmed and moistened; it is fitted with thermometers, and so regulated by a movable lamp that air saturated with moisture is supplied at a uniform temperature of 40° to 50° C. The object of the inhalation is to cause dilatation of the vessels of the pulmonary vesicles, and thus introduce a larger quantity of blood into the lungs without increasing the frequency of the pulse. By this means it is hoped the aëration of the blood would be promoted, in spite of the slight rarefaction of the heated air, and the still healthy portions of lung would gradually gain in vitality from improved nutrition, so as to be better able to resist the inroads of bacilli, and to complete the absorption or resolution of the lowly organized products which perpetuate the disease. The cases published by Dr. Krull are all examples of advanced phthisis, and his results have been such as to insure a wider trial of his method; but he looks for even greater success in cases in earlier stages. The treatment is carried out by administering, once or twice daily, an inhalation at 43° to 44° C., for a period of thirty-five to forty minutes, the patient breathing in, at natural intervals, through the mouth and out through the nose. All medicinal treatment is discontinued, a daily walk in the open air (with all precautions), occasional tepid baths and skin-rubbing, and properly regulated diet, being the only adjuncts. After each inhalation the patient reclines on a sofa for an hour or two.—*British Medical Journal.*

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 18, 1888, *to November* 24, 1888.

Alexander, Richard H., Lieutenant Colonel and Surgeon. By direction of the Secretary of War, leave of absence for four months is granted, to take effect from the date of his relief from duty as Medical Director, Department of Arizona, by Lieutenant Colonel **Joseph R. Smith**, Surgeon. Par. 11, S. O., 268, A. G. O., Washington, November 16, 1888.

Smith, Lieutenant Colonel. After being relieved by Lieutenant Colonel **Alden**, will report in person to the commanding officer, Department of Arizona, for duty as Medical Director of that Department, relieving Lieutenant Colonel **Richard H. Alexander**. Par. 10, S. O. 268, A. G. O., Washington, November 16, 1888.

Alden, Charles H., Lieutenant Colonel and Surgeon. Is relieved from further duty at the U. S. Military Academy, West Point, N. Y., and will report in person to the commanding general, Department of Dakota, for duty as Medical Director of that Department, relieving Lieutenant Colonel **Joseph R. Smith**, Surgeon. Par. 10, S. O. 268, A. G. O., Washington, November 16, 1888.

Smart, Charles, Major and Surgeon. By direction of the Secretary of War, will proceed to Milwaukee, Wis., to represent the Medical Department of the Army at the meeting of the American Public Health Association, in that city, November 20 to 23, 1888, and upon the adjournment of the Association will return to his proper station. Par. 2, S. O. 268, A. G. O., Washington, November 16, 1888.

Newton, Richard C., Captain and Assistant Surgeon. By direction of the Secretary of War, leave of absence for four months is granted. Par. 16, S. O. 272, A. G. O., Washington, November 21, 1888.

Wood, Marshall W., Captain and Assistant Surgeon. By direction of the Secretary of War leave of absence granted in special orders, No. 257, November 3, 1888, from this office, is extended ten days. Par. 12, S. O. 270, A. G. O., Washington, November 19, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending November 24, 1888.

Heffinger, A. C., Passed Assistant Surgeon. Ordered to the U. S. S. Kearsarge.

Bryant, Patrick H., Assistant Surgeon. Ordered to the Naval Hospital, Brooklyn, N. Y.

McMurtrie, Daniel, Surgeon. Ordered to the U. S. Receiving Ship Vermont.

Drennan, M. C., Surgeon. Detached from the Vermont and to the Atlanta.

Winslow, G. F., Surgeon. Detached from the Atlanta and placed on waiting orders.

McClurg, W. A., Passed Assistant Surgeon. Detached from the Tallapoosa and to the Kearsarge.

Von Wederkind, L. L., Assistant Surgeon. Ordered to the New Hampshire.

Heffinger, A. C., Passed Assistant Surgeon. Detached from the Kearsarge and to the Tallapoosa.

Stephenson, B. F., Surgeon. Detached from the Navy Yard, Boston, and to the Wabash.

Oberly, A. S., Medical Director. Ordered to the U. S. S. Richmond.

Jones, W. H., Surgeon. Detached from the U. S. S. Richmond and wait orders.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending November 24, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	17	4
Scarlet fever	147	26
Cerebro-spinal meningitis	1	0
Measles	233	7
Diphtheria	114	25
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

For Uræmic Insomnia and for urgent uræmic symptoms of all kinds, Dr. William H. Porter gives ¾ grain of pilocarpine hypodermically, and claims to get rapid relief. He believes that the drug acts as a vaso-motor stimulant and increases blood-pressure, and that the lethal effects of the drug are due to the usage of too small a quantity, which acts in a directly opposite manner, and paralyzes the vaso-motor system and thus causes lowering of blood-pressure. Dr. Porter relates several interesting cases.—*Canada Lancet.*

One Source of Caffeine.—It is said that between 3,000 and 4,000 lbs. of caffeine are annually made in Germany from damaged tea which has been rejected by the British custom-houses.

To Cut the uvula, draw it forward and cut, as this makes an oblique incision, and the raw surfaces are not scraped every time the patient swallows, as would be the case if cut horizontally. Spray with twenty per cent. solution of cocaine. (Sajous.)

Another Fasting Man has begun a thirty-day fast at Edinburgh. The man's name is Alexander Jacques, and he expects to show the utility of a certain herb by which he expects to sustain himself. He will, at least, give his herb a big advertisement.

Ministerial Risk—"I'm very glad to have been of any comfort to your poor husband, my good woman. But what made you send for me, instead of your own minister?" "Well, sir, it's 'typhus' my poor husband's got, and we dinna think it just reet for our ain minister to run the risk!"—*Punch.*

The Expulsion of the Placenta.—The manner in which the placenta is expelled is a subject of high interest, both to the scientific obstetrician and to the practitioner. Baudelocque maintained that the placenta was detached by the effusion of blood between its inner surface and the uterine wall. This theory implied that the uterine muscular apparatus played a passive part in the process, and that flooding was, so far as needed for detaching the placenta, a physiological and not a pathological process. Mathews Duncan's theory, now generally accepted, is very different. The uterus, he still insists, is active in expelling the placenta. Its retraction and contraction progressively diminish the uterine cavity until the placenta is forced beyond the os. Effusion of blood may occur, but that accident is not essential. According to Baudelocque's theory, the fœtal aspect of the placenta should present; after Duncan's doctrine, either side or the edge may present. Dr. Auvard, who has recently considered the whole question (*Archives de Tocologie*, August, 1888), dwells on the fact that on Duncan's theory the presentation of the fœtal aspect is comprehensible. The placenta is first detached by uterine contractions, and blood is accidentally effused between the uterine wall and the placenta during muscular relaxation. A contraction follows, and presses on both the clot and the placenta, the latter turns over and its fœtal aspect presents. Even without hemorrhage the placenta detached from the fundus may fold in on its uterine face, and thus come to be expelled with its fœtal aspect foremost. M. Varnier has described a case where a clot was discovered, and where the placenta was found curled in on its uterine aspect. He believed that this case verified Baudelocque's theory, but Dr. Auvard disagrees with him, and notes that if true it ought to explain every case. Yet the hemorrhage theory could not, he says, explain the detachment of a placenta prævia at the moment of birth. Again, in some labors, there is little or no hemorrhage, so the placenta must be detached otherwise than by blood. Dr. Auvard distinguishes two mechanisms by which the placenta is retained. Bandl's ring may close up, so as to make an hour-glass contraction, completely imprisoning the placenta in the upper or thick segment of the uterus. This Dr. Auvard terms *emprisonnement*. Sometimes, however, an accessary ring forms by contraction high in the upper uterine segment, and contracts sufficiently over the edges of the placenta, so as to retain it, as a stone is retained in the bezel (Fr., *chaton*) of a ring. Hence Dr. Auvard gives to this variety of retained placenta the name *enchatonnement*. He finds that it is much rarer than "imprisonment." When it exists the normal uterine circle is detected above the flaccid lower segment, and the finger passes into the cavity of the upper segment till the placenta can be felt retained high up in this segment.—*The British Medical Journal.*

A Heavy Indictment against London.—The *British Medical Journal* concludes an editorial article suggested by the recent Whitechapel murders in the following strong language: "Here, then, are three chief defendants in the indictment which this series of murders opens against London. Ourselves, the great public of London, stand first in the dock, convicted by flagrant and horrible proof of indifference to the physical and moral degradation of our fellow-citizens; convicted of tolerating darkness, filth, crime, and obscenity as ordinary incidents of metropolitan life; standing aside with intellectual apathy, with pockets closely buttoned, and with minds intent on our own pleasures and businesses, and looking on indifferently at the work of the few devoted toilers who have done so much to redeem London from these horrible disgraces. Next, our municipal authorities stand charged with indifference to the lighting, paving, and cleansing of their streets and courts, and with permitting the inhabitants to carry on a traffic prohibited by law, and one which it lies with them to suppress. Lastly, the police need to be quickened by a higher sense of public morality, to be strengthened in number, and to be encouraged and commanded to a much stricter exercise of their ordinary duties as patrols. At present, night charges are rather discouraged; the opposite tendency ought henceforth to prevail. But this is a measure of repression which can only be effectual if it be accompanied and preceded by an unwearying and unstinting effort to remove the conditions under which criminal and degraded conditions arise. While earnestly hoping, therefore, that the secret of these assassinations may, as there is some reason to hope, be quickly unravelled, there remains the yet more ardent desire that the lessons taught by these horrors will be enduring, and will have a fruitful effect on the social well-being of the metropolis."

Cocaine Conjunctivitis.—Dr. Charles Rice, of this city, referring to the recent paper by Dr. Kipp, writes: "I desire to say that my attention has been drawn repeatedly, by several prominent ophthalmologists, to the very peculiar effects produced by the simultaneous, or nearly simultaneous, use of silver nitrate and cocaine muriate. In some cases these substances produced a most alarming condition of the eyeball, such as intense inflammation, purulent discharges and sloughing. A careful chemical examination of the substances employed showed them to be pure. There appears, therefore, no other explanation possible than a physiological one, namely, a peculiar susceptibility of the tissue, the blood-vessels of which have previously been affected in the well-known way by cocaine, to the action of nitrate of silver. The fact of this peculiar action appears to be beyond doubt, but the explanation is merely a guess.

Mare-meat.—Dr. Huidekoper, of Philadelphia, recently had a very fine mare, and still more recently a very fine dinner, the latter being tendered to some friends at the Philadelphia Club. The mare was served up at the dinner as one of the courses, the part served being, naturally, a *filet.* In explaining the nature of their dinner after it was over, Dr. Huidekoper says: "All horse-meat is as good as beef. It is a pity that horse-meat is not eaten in this country. The horse would not have to be worn out and sold to hucksters at $10 and $12, when they would bring good prices for meat. The people in this city eat beef a great deal more unfit for food than good horse-meat. I can go to the stock-yards in West Philadelphia and pick out a dozen head of cattle any morning that are utterly unfit to eat, that are sent to market. There is no inspection of meat in this city and the law is violated every day. The only beef that is properly inspected is that eaten by the Hebrews, which is killed according to their rule. The Council of the Veterinary School of Belgium even recommended dog-meat for human food after being properly inspected. There are 125,000 human deaths in this country every year from tuberculosis, and nearly one-half of them are the direct result of eating diseased beef."

Boiled Water as an Aseptic.—Microbian cultures flourish in the most concentrated solutions of carbolic acid; and this is also true of sublimate solutions actually as strong as usually recommended. The accidents occasioned by corrosive sublimate, by carbolic acid, and even by iodoform, are so frequent and so well known, in the meantime, that one cannot too warmly urge upon surgeons the use of simple water, which, after filtration and boiling, at 100° F., or, better, at 120° F., if one has the proper apparatus, is certainly the best aseptic we have at our disposition. While solutions of hydro-chlorate of morphine for hypodermic use, made according to the old method, with distilled water, are full of micro-organisms and of microbes at the end of five to ten days of use, they are preserved pure and perfectly limpid during weeks or even months, if water be employed which has been filtered and boiled.—*Gazette de Gynécologie.*

Oxy-propylen-di-iso-amylamine.—A new artificial alkaloid has lately been discovered, to which the name of *oxy-propylen-di-iso-amylamine* is given. It is prepared by the action of hydrochloride of propyl on di-iso-amylamine. It forms an oily, colorless liquid, only slightly soluble in water, but soluble in alcohol, and forming very soluble salts with acids. The physiological action of this body has been investigated by Louise. On the nervous system it acts something like atropine, but in toxic doses causes epileptic seizures of two kinds. In moderate doses it is a powerful cardiac tonic, and an energetic stimulant of the circulation and the cerebro-spinal centres. In its action on the heart it resembles atropine, paralyzing the inhibitory apparatus and increasing the action of the accelerating nerves. There is remarkable augmentation of the intravascular pressure, and marked elevation of the temperature of the body in cases of acute intoxication. The toxic dose for a man is about half an ounce.—*The Provincial Medical Journal.*

Sir J. Fayrer on Cholera.—In an address on the natural history and epidemiology of cholera (*Medical Press*) Sir Joseph Fayrer says that, although much remains to be known about the causation of cholera and its apparent caprices in incidence and diffusion, yet, from what experience and observation have taught us, we seem to be warranted in stating the following to be facts with reference to the disease: 1. That cholera has been present in India and other countries from the earliest times, and that isolated cases occur in almost all countries. 2. That cholera is always present, not only in certain parts of India, but elsewhere, and that in India outside these areas its prevalence varies in different years, and according to the season of the year. 3. That cholera does not attack all the places within an epidemic area. 4. Meteorological changes produce sudden alterations in the activity and intensity of an outbreak. 5. That the rate and direction of an epidemic are not influenced by facilities of communication or by the greatest streams of human traffic, the opening of the Red Sea route, *e.g.*, not having increased its diffusion. 6. That the cases are more frequent and more severe at the commencement than in the continuance of an outbreak. 7. That hygienic measures afford the greatest security, but are not an all-powerful safeguard against cholera; local insanitary conditions and impure water favor its incidence and increase its intensity; that it is important to check all diarrhœa in times of cholera prevalence. 8. That cordons and quarantine have utterly failed to prevent the spread of cholera, but, on the contrary, have done harm. 9. That to enter an area over which cholera is present, or to travel within that area, is especially dangerous to a new-comer, while residents whose circumstances of living are favorable have a better chance of escape 10. That removal is the best course when cholera attacks a regiment or other body of men. 11. That attendants on the sick have not suffered more than others. 12. That impure water, irritating articles of diet, unripe fruit, saline aperients, are liable, during cholera prevalence, to bring on diarrhœa and the disease. 13. That fatigue, exhaustion, fear, and anxiety are powerful predisposing causes. 14. Many circumstances attending the outbreak of the disease and the pathological conditions then developed seem opposed to a specific poison as being the cause of the disease. 15. Having suffered from cholera gives no immunity from recurrence of the disease.

A REMARKABLE POST-MORTEM.—Dr. Dauscher records the following remarkable case: A man, aged thirty-five, was suddenly thrown down by a mass of earth, which fell from a height of about sixteen feet. It struck him upon the back, covering first his feet, then his legs and abdomen, and lastly the thorax, leaving the head and neck free. Workmen at once proceeded to extricate him, but death had taken place before this could be accomplished. At the autopsy the author was surprised to note a large swelling, about the size of an adult skull, in the neck, and extending toward the right shoulder. Upon examination this swelling proved to be the two lungs and the heart, which had been thrust through the upper wall of the thorax. Beyond this the man exhibited no further signs of injury. The abdomen, however, was greatly depressed, and on laying it open the viscera were found to have been displaced into the thorax. The diaphragm was ruptured in several places, and notably around its attachment. The thorax was almost completely filled with the abdominal organs. The spleen and liver were both ruptured, but neither the stomach nor intestines had received any injury. The heart was small, the large vessels and trachea were unwounded, the lungs collapsed, and brain and cranium normal.—*Medical Press.*

CLIMATE FOR CONSUMPTIVES.—Dr. Knight, in the *Boston Medical and Surgical Journal*, makes the following suggestions as to a suitable climate for consumptives: (1) Those presenting the earliest signs of chronic tuberculosis of the apex, with morning cough, but little general disturbance, should live out-doors in Colorado or New Mexico; at an altitude of 4,000 to 8,000 feet. (2) More advanced cases, with some consolidation, but no excavation, if the pulse and temperature range below 100, may go to the same localities; but if not, to Aiken, or the pine woods of South Georgia. When the morbid processes become quiet, a move may be made to the higher altitudes. (3) Hemorrhagic cases should also go to the high altitudes. (4) Advanced cases with hectic or cavities had better stay at home, unless they are possessed of sufficient means to obtain home comforts elsewhere, when they may be sent to Florida. (5) Cases of acute general infiltration should be kept at home. Those commencing like acute pneumonia should stay at home till the acute symptoms subside, and then remove to some low, dry place; cautiously changing to more elevated localities. Cases of acute exacerbations should pursue the same course. (6) Pneumonic cases, if young, should be sent up the hills. If over fifty, or with dilated heart, or very harassing cough, Southern California offers a suitable climate. (7) Those who are threatened with tuberculosis after pleurisy or pneumonia should go to high localities. (8) Laryngeal tubercle. For these cases Southern California answers well. (9) Complications may alter these rules. Dilatation forbids high altitudes, while other cardiac cases should be carefully watched. Acute nephritis is aggravated by high altitudes, but chronic Bright's disease is benefited. Patients with intestinal ulcers do badly everywhere.

THE RECOGNITION OF HUMAN BLOOD-STAINS BY THE MICROSCOPE.—At a meeting of the Medical Jurisprudence Society of Philadelphia, the important and interesting subject of the recognition of human blood was under discussion. (*The Philadelphia Medical Times*). The subject was introduced by Dr. Formad, the Coroner's physician, who read a paper entitled "Microscopical Examination of Blood from a Medico-legal Stand-point." An incidental feature which gave special importance to the paper was the statement by Dr. Formad, which he was reported as having made on the witness-stand in a recent trial for murder in this State, that he could always recognize human blood by the microscopic appearances and tests. This advanced position, however, was not sustained by the remarks of the lecturer, and, when taxed with it during the discussion, he denied ever having made such a positive statement, and explained that the stenographer had failed to get all of the answer he had given to the interrogation in the trial referred to. The drift of the discussion was decidedly opposed to the claim that human blood-clot could be absolutely recognized beyond the possibility of mistake. In many cases, it is true that valuable evidence of a negative character can be thus obtained, but the most that can be affirmed at present of any given specimen is, that the result of the examination is consistent with the theory that the stain was due to human blood, and that it was derived from some of the higher mammals.

TREATMENT OF NÆVUS BY ETHYLATE OF SODIUM.—The treatment of nævus by means of ethylate of sodium was advocated by Dr. B. W. Richardson in an early number of the *Asclepiad*, and in the current issue of this serial its author again reverts to the subject. The method as now employed is as follows: The surface of the nævus is first dried with a piece of cotton-wool, and is then thoroughly coated with the ethylate, applied with a good camel-hair brush, the use of a glass rod not being really essential. The pain which generally ensues is by no means considerable, and soon a few drops of watery exudation appears on the reddened surface, which subsequently becomes dry and pallid. In a few hours a scab forms, which gradually hardens, and on the third day a fine needle with cutting edges is passed through it, and used to break up the vascular surface beneath. On applying firm pressure now to the upper surface a drop or two of blood escapes, and at once a piece of lint steeped in styptic colloid is applied to control the bleeding, on the cessation of which a drop of the ethylate solution is inoculated into the nævus through the punctured opening, a new layer of it is painted over the crust, and the crust left for another four days, when, if firm and dry, the cure is complete; otherwise a repetition of the puncture and inoculation may be requisite.

HINTS FOR THE TREATMENT OF SLEEPLESSNESS.—The following *résumé* of an article by Dr. Eccles, on the treatment of sleeplessness, is published in the current number of *Gaillard's Medical Journal:* 1. *Hot bath,* taken just before settling quietly for the night, is most valuable in producing a dreamless sleep, though this does not usually last more than four hours, and is sometimes followed by a period of great wakefulness, relieved only by a short morning doze.. Method of giving the bath most important. Bath-room should be at temperature of 65° F., and this to be raised during bath to 70° F. Patient to be at once stripped, and then the stooped head and face rapidly douched with water at 100° F., to dilate brain vessels; next whole body, except head and face, to be immersed in bath at 98° F., and this temperature rapidly raised to 105°–110° F. In about eight to fifteen minutes, when the at first accelerated pulse has fallen to a slow, full, steady, and compressible beat, the patient must be slowly raised, closely wrapped in warm blankets (a loose pyjama suit is a good contrivance), and conducted to the bedroom without any haste and at as small personal effort as possible. On reaching the bedroom he will be dry. Let him then at once don his night-clothes and immediately lie down with the head well raised, a hot bottle to the feet, and the body well covered with bedclothes. The bath probably acts by reducing the supply of blood to the whole of the brain, thus decreasing the functional activity equally throughout, and so placing it in the most favorable condition for complete functional rest, to the exclusion of the partial activity of certain centres which would induce dreaming. It has proved most useful for the relief of disturbed sleep in persons who have either ceased to be influenced by ordinary hypnotics, or in whose cases their use is contra-indicated. The bath itself, however, is contra-indicated in extreme anæmia, emaciation, aortic valvular disease, and atheroma.

2. *Massage at bedtime.*—Valuable in organic cardiac mischief, and in the very large number of cases in which functional weakness of the heart and circulation generally is a feature of the nervous debilitated constitution. Two cases of aortic regurgitation mentioned, in which permanent benefit resulted, and one of aortic aneurism where the improvement was only temporary. On conclusion of the kneading the patient must at once compose himself to sleep. Its performance must be rapid, commencing with the abdomen and passing to the back, arms, and legs, with as little exposure of the parts to the outer air as possible, so that a layer of warm air may be maintained between the closely covered limbs and the bedclothes. The manipulations should be directed not so much to the evacuation of the lymphatic and venous vessels of the parts dealt with, as to the rapid and sufficient stimulation of the sensory nerves with the dilatation of the arteries over as large an area as possible. This kneading no doubt acts in the same way as tapping the abdominal parietes of a frog, which Goltz showed greatly dilated the abdominal vessels and distended them with blood, whilst it reduced the frequence of the pulse.

3. *Warm abdominal compress.*—Take two pieces of twilled calico, half a yard wide and four yards long; roll these up lightly and raise them to a great heat in a closed earthenware vessel in a hot oven. Immerse as much of one as is necessary to cover the abdomen in water, and apply closely to the abdomen, then rapidly and firmly roll the rest of the bandage round the abdomen and loins; take the other hot bandage out of the earthen vessel and wrap it firmly round the first. In this way heat and moisture are kept applied to the abdominal walls, keeping up the free circulation of blood and soothing the nervous system. Schüller put a warm compress on the belly of a rabbit, and having removed the cranial walls he noticed that an immediate and long-continued contraction of the meningeal vessels, with slowing of the cerebral movements resulted.

4. *The wet pack.*—This is most useful in those cases of erethetic neurasthenia resulting from prolonged overwork, mental distress, morphine habit, chloral drinking, and chronic bhang-poisoning. Any immediate beneficial results cannot be expected in these cases. The mechanical stimulus of massage temporarily excites rather than soothes the ill-balanced nervous system. Drugs are contra-indicated and moral suasion is useless. Should the patient's surface temperature be subnormal (*i.e.*, foot under 90° F. and palm less than 95° F.), moderately firm friction of the limbs and trunk should be employed to raise the superficial warmth. The bladder should be evacuated. The patient should leave the pack as soon as the previously retarded circulation begins to be accelerated. The night-clothing should be well warmed and put on as quickly as possible. With all four the recumbent position must be maintained in a quiet, cool, well-ventilated room, the diet must be carefully modified, and daily massage performed.

AGE AND CHILD BEARING.—There has always been much mystery connected with the old maid and her first child. Old women shake their heads wisely and solemnly when a woman above thirty marries and comes to her first childbed. Eckhardt has given this subject considerable attention (*Zeitschrift für Gebürtshulfe und Gynækologie,* xiv., 1, p. 44). His field for observation has been an extensive one, viz., the Gynecological Klinic of Berlin. He finds the mortality of the children increases in proportion to the age of the mother. His statistics of mortality of the children reach 19.81 per cent., corresponding very nearly with those of Kleinwachter, 19.26 per cent. The mortality among old primiparæ is nearly three times as great as among the young primiparæ. He observed a regular increase in the rate of mortality when he compared primiparæ in groups of succeeding four years, from twenty to forty years. He found turning done more frequently as age increased among primiparæ, but seldom done after forty years. Forceps deliveries occur three times, and perforation five times as often in old primiparæ as in young. The per cent. of all these operations increases with the age of the patient, and above forty years reaches 58 to 60 per cent.—MCKEE, *Cleveland Medical Gazette.*

DO CONTRACTED PELVES have an influence on the sex of the child? This is a question of considerable interest and has been given some attention. Olshausen, of Berlin, in a series of 521 deliveries of women having contracted pelves, found 211 girls and 310 boys, *i.e.*, 100 to 147. Ahlfeld arrived at much the same results, viz., 133 boys to 100 girls, or 150 to 100. Dohrn (*Zeitschrift für Gebürtshulfe und Gynækologie*, xiv., 1, p. 80) has made the last thorough experiments on the subject in the obstetrical clinic of Königsberg. He collected statistics of 450 deliveries in women who had narrow pelves; 224 were girls and 226 were boys—100 to 100.6. The other deliveries in this clinic were in the proportion of 100 to 101.6. Dohrn is of the opinion that a narrow pelvis has no influence on the sex of a child.—MCKEE, *Cleveland Medical Gazette.*

THE ILLEGALITY OF SICKNESS.—It seems to be considered as much a crime for a person in a summer resort to become sick as it is for the physician in attendance to seek to save others from exposure to contagion. The *Sanitary News* says that at Hamburg-les-Bains this summer two rich New Yorkers—the Messrs. Harriman—were taken down with slow fever in an apartment of the house opposite the Kursaal. When they recovered the landlord demanded two thousand marks for damages, which, after consultation with Frankfort lawyers, they had to pay.

WHAT THEY THINK OF EACH OTHER.—"What is the difference between the allopaths and the homœopaths?" asked Mrs. Cumso of her husband. "Oh," he replied, "the allopaths think the homœopaths are not ortho-docs." —*Life.*

OXALURIA, ESPECIALLY IN ITS RELATIONS TO URIC ACID.

By DEBOUT D'ESTRÉES, M.D.,

CONTREXVILLE, FRANCE.

"The excessive production of oxalate of lime in the economy is a subject the explanation of which offers one of the most difficult problems to the physician."

So wrote our deceased master, Professor Bouchardat. To-day the problem is still not solved, and I must confess that after a professional experience of twenty years in a town where, on account of its mineral springs, patients afflicted with gravel congregate, coming from all parts of France, I am still unable to clearly define the principles which govern the formation of oxalate of lime in the human system.

It is a fact that in our country deposits of the oxalates are as rare as they are common in the United States, and it is for this reason that I am eager to bring before you, for your judgment, the paper that I have the honor to submit this evening.

The proportion of patients suffering from oxaluria in France is forty-seven per thousand of gravel, as observed at Contrexville, while it is eighty per cent. among those American patients, who, suffering from gravel, came under my care on the continent.

The uric-acid calculi so common among us are, on the contrary, the exception with those of your countrymen who were under my professional care.

My experience concurs with that of the best authorities of both nations; for while in Paris Professor Bonehardat found, on analysis, calculi in one hundred and forty-three cases in a thousand, and Dr. Leroy d'Etiolles thirty-three times in two hundred and fifty-two cases, with oxalate of lime as a neucleus, in *this* country Dr. Bigelow found forty-three cases in a hundred.

Before we look for the cause of these differences let us make a rapid review of the principal theories which have been advanced from time to time to explain the formation of oxalate of lime, bearing in mind that this salt, when chemically pure, is white, while that of the calculi, of which it is a component part, is in nearly every instance black (mulberry calculus), owing to the presence of the coloring matter of the blood.

I have, however, occasionally met with some forms presenting a white color, as illustrated by the two specimens which I submit to you herewith. But in oxaluria renal hæmaturia is the rule, while in uric-acid gravel it is the exception.

Various theories have been advanced to explain the formation of oxalate of lime in the system. Prout (an English author) considers the oxalate of lime so produced as the result of imperfect assimilation of oxalic acid contained in the food; this being true also in the case of sugar, and possibly albuminous and oleaginous food.

The German chemist Lehmann has advanced another theory; he admits that the oxalate of lime may be traced to vegetable food containing oxalic acid, and that the same result might be produced by beers rich in carbonic acid, by the double carbonates, and by the alkalis in combination with organic acids. Aside from the oxalate derived from ingesta, Lehmann admits that a certain quantity is formed spontaneously in certain pathological conditions, and he attributes its formation to a modification of the respiratory function.

The carbonic acid in this case mingling with the blood in excess would prevent its complete oxidation. We will not dwell on the theory of Schmidt, who looked for the origin of oxalate of lime in the mucous membrane of the urinary organs, nor on the theory of another German author, Beneke, who is of opinion that oxalic acid is the direct outcome of a suspension in the successive physiological transformations which nitrogenous foods undergo. To this author, therefore, oxalic acid would appear to be an element existing temporarily in the urine in the physiological state, finally becoming oxidized, and undergoing a change into carbonic acid. When through some cause this oxidation is prevented, oxalic acid appears in the urine.

The exaggerated ingestion of nitrogenous food, want of exercise in the open air, catarrhal conditions of the mucous membrane of the stomach, are some of the causes assigned by this author. In fine, the nervous system is not a stranger to the production of oxaluria. All the causes which depress it cause a delay in metamorphosis, and stand in causative relation to the production of oxalic acid.

But the exaggerated ingestion of nitrogenous food, or lack of exercise, are just as likely to produce uric-acid gravel. Why, then, should there be a formation of oxalic acid?

According to Dr. Beneke this would depend on the time at which the transformation of nitrogenous materials in the blood into urea ceased, when there would be at once a decrease of urea, uric acid, and oxalic acid. According to his views the uric acid derived from the nitrogenous materials of the blood divides into two parts, one being transformed into urea and oxalic acid, the other eliminated in the form of uric acid. In the physiological state the oxalic acid would be transformed into carbonic acid.

But let us suppose that, through one of the causes cited above, oxidation be prevented, then there would be elimination of oxalic acid. Therefore, according to that author, the matter resolves itself into a simple question regarding the precise time at which the transformation ceases.

According to Maclagan (an English author), it is the nervous system which is active in the genesis of oxalate of lime, especially when there is a retardation of the respiratory function.

Owen Rees thinks that the oxalate of lime does not exist primarily in the urine, but that its presence there is due to a secondary formation, because of a simple molecular transposition which takes place between the elements of uric acid and the urates.

I will not dwell upon the works of Vulpian and Gallais, in France, and of Ralfe, in England, but will conclude with the opinion of Professor Bouchard, which is that the oxalate of lime increases in all diseases in which there is a disturbance of the processes of nutrition, and that acid fermentation, with production of oxalic acid, takes place in children into whose food potatoes enter largely, retarding or interfering with the natural functions of the digestive organs, fermentation commencing in the stomach and continuing in the intestinal tract, the alkaline juices of which it neutralizes. This explains the frequency of oxaluria among the children of poorer classes.

I will not encroach upon your time with any further quotations, but will proceed to formulate what I believe to be, in our present knowledge, the nearest approach to truth, in this most interesting question regarding oxaluria.

1st. Oxalate of lime is a body that may be present in normal urine to a greater or lesser extent, owing to the influence of certain foods.

2d. Uric acid is frequently found, together with oxalate of lime, in urinary sediments in gravel as well as calculi.

3d. Oxalic acid owes its existence to the presence and incomplete oxidation of uric acid.

4th. Alkaline mineral waters having lime as a base, present the most effective means at our command to cure oxaluria.

This last assertion is to be credited to Dr. Bouchardat, professor of hygiene, faculty of Paris. No evidence is required to establish the correctness of the first proposition. You will readily find crystals of oxalate of lime in urine twenty-four hours after the ingestion of food containing the salt in large quantities, as, for instance, rhubarb, tomatoes, sorrel, etc.; indeed string beans, oranges, celery, green fruits, apples, and water-cress contain it in notable quantities.

The second point touching the co-existence of uric acid and oxalate of lime in the urine does not call for special proofs. No one who has made an analysis of the urine of a patient suffering from gravel has failed to discover, on microscopical examination, crystals of oxalate of lime associated with uric acid. Moreover, I will venture to say that there is no one present who has not met calculi with a nucleus of oxalate of lime surrounded by uric acid, and those rarer specimens in which deposits of oxalate of lime were found surrounding a nucleus of uric acid.

The specimens of gravel which I brought from Contrexville, and which I have the honor to place before you, and which were voided per *vias naturales*, show two rather exceptional features. In one you will find that oxalate of lime is deposited on two sides of a uric-acid calculus, in the other the stone seems to be formed of two distinct parts, namely, uric acid and oxalate of lime.

Regarding the third statement, Wöhler's experiments would seem to confirm this. He injected uric acid into the veins of dogs, employing the urate of ammonia, and as a result found oxalate of lime in the urine. This justifies the inference as above regarding the presence of this salt in man.

The records of the clinic at Contrexville will serve to further demonstrate the correctness of this assumption.

In fact, without citing cases which would increase the length of this paper beyond its scope, I think that the one fact which those of our confrères, who, like Dr. Keyes, visited the Vosges last year, were in position to verify, will suffice. A patient presents himself whose urine is of high specific gravity, from 1.028 to 1.032 (Sir Alfred Garnod spoke to me of a case in which it had reached 1.040), and showing on analysis the presence of crystals of oxalate of lime alone. Eight days later the specific gravity of the urine is from 1.023 to 1.026, and uric acid is discovered in the form of fine crystals, together with oxalate of lime. Fifteen days later the specific gravity has fallen to 1.015, and on microscopic examination uric acid is found exclusively. What further proof is necessary to show that oxaluria and the uric-acid diathesis are of common origin? The same facts obtain in diabetes, as explained by me in an article in *The Lancet* of May 22, 1887.

Why, then, does the French patient present the complication of uric acid, and the American oxalate of lime? May I be permitted to suggest the causes, and ask you whether you agree with me?

Uric acid is found in patients ill through heredity, overfeeding, and sedentary habits.

Oxalate of lime is found in dyspeptics, in men whose nervous system is exhausted, and in those who take large quantities of food containing the salt.

Is not this the case with your countrymen?

While the French, sedentary by taste or by profession, give themselves up too willingly to high living, the Americans live too fast, fatigue their nervous system beyond reason, without giving their digestive apparatus that proper care and attention which it deserves.

I believe that I am correct in formulating this opinion, based upon an experience of twenty years in cases of gravel, and I lay it before the members of your honorable body, whose kindly aid and valuable counsels I trust may be accorded me.

ON THE MANAGEMENT OF PROGRESSING CEREBRAL HEMORRHAGE.[1]

By ANDREW H. SMITH, M.D.,

NEW YORK.

It not infrequently happens that a physician sees a case in which hemiplegia from cerebral hemorrhage has just occurred, and in which the patient is still conscious and the more pronounced symptoms of intracranial pressure are not yet developed. Perhaps, even while he is looking on, these symptoms begin to appear, mental confusion passes into coma, the respiration becomes stertorous, there is dilatation of one or both pupils. In a word, the first symptoms, those of shock to the brain, have been replaced by those of compression. Now this compression, as we all know, is the result of effusion of blood within the unyielding skull, and the degree of compression will be in proportion to the amount of blood effused. Excluding cases in which there has been laceration in important brain-regions by the force of the out-pouring blood, the prognosis will be determined mainly by the amount of blood which escapes from the ruptured vessel, and the consequent degree and duration of the cerebral compression. Hence all our efforts should be directed to limiting the effusion to the smallest amount possible. Upon our success or non-success in doing this will depend in all probability the recovery or death of the patient.

But it is evident that our efforts in this direction must be guided by a correct appreciation of the manner in which hemorrhage in general is spontaneously arrested. In the case of wounds, for example, this arrest takes place through various agencies. First, if the vessel be small and if it be completely divided, the irritation of the injury produces a contraction of the circular fibres which greatly diminishes, if it does not entirely obliterate, the lumen of the cut extremities of the vessel. Second, the same cause leads to a longitudinal retraction of the vessel within its sheath, and the unoccupied portion of the sheath then affords a receptacle in which the effused blood lingers and becomes coagulated, thus forming a tampon against the bleeding orifices. Third, if there be not a free escape for the blood to the surface it accumulates in the tissues surrounding the vessel, and, exercising pressure upon the divided extremities, acts mechanically to close them. Fourth, if, in spite of these provisions for arresting the flow of blood, the hemorrhage still continues, the heart's action ultimately becomes enfeebled, thus diminishing the *vis a tergo* in the wounded vessel, and giving a better opportunity for the agencies already described to effect their object. This is especially the case when the hemorrhage results in syncope.

Now let us see how many of these provisions are available for the spontaneous arrest of cerebral hemorrhage as it commonly takes place. In the first place, the rupture occurs, in the majority of cases, not in the continuity of the vessel but in the wall of a minute aneurism formed upon the vessel. This wall is practically destitute of contractile tissue, and the vessel, not being entirely divided, retraction does not take place. Hence nature's first two provisions for the arrest of bleeding are of no avail. Secondly, even when the rupture takes place in the substance of the brain, the surrounding tissue is too soft to offer any considerable resistance to the escape of the blood, and therefore the third provision is to a great degree inoperative. The fourth, that of diminished cardiac action, is also useless, since the loss of blood is never sufficient to bring it into play.

---

[1] Read before the Practitioners' Society, November 2, 1888.

Hence we see that none of the methods by which hemorrhage in other situations is spontaneously arrested is fairly applicable to cerebral hemorrhage as it usually occurs. There is, however, a limitation imposed upon such hemorrhage, viz., that which results from the rigidity of the bony wall in which the brain is encased. When the brain has been compressed to the utmost, and there is no more space within the skull into which blood can be infused, the hemorrhage must of necessity cease.

Now, while we see in practice many cases in which the symptoms indicate the escape of only a very limited quantity of blood, and in which we must assume either that the rent in the vessel was extremely small or that the resistance of the surrounding brain-matter was sufficient to restrain the extravasation, still, it is much more frequently the case that the hemorrhage goes on until unmistakable pressure-symptoms are developed. In these cases it is highly probable that the flow ceases only because there is no room for more blood within the skull.

Aside from the immediate harm done by this pressure, the ultimate results of this large effusion are of the gravest moment. The larger the clot the longer will be the time required for its absorption, and the longer the brain will be exposed to the disturbing influence of its presence. Indeed, as already remarked, the gravity of the prognosis, other things being equal, is directly in proportion to the extent of the hemorrhage.

If, then, we have reason to believe that in the patient before us the bleeding is still going on, what measures are to be taken to arrest it? The means employed must be such as are prompt in action, for minutes, even fractions of a minute, are of value. It is usual to place the patient with the head raised and to apply cold to the vertex. Formerly a vein was opened, but this is now seldom resorted to. Purgatives or enemata are often employed. Perhaps some would give ergot, on the general principle that it tends to restrain internal hemorrhage.

Let us consider these means in their reverse order.

As to ergot, it is of value only in hemorrhage from the capillaries or arterioles. It constricts the latter, but in cerebral hemorrhage, if the diseased condition of the vessel left any muscular fibre to act, the constriction would be more likely to be on the distal than the proximal side of the opening, and in that case would only aggravate the bleeding. But more important still is the fact that ergot increases greatly the vascular tension, and this would add to the force by which the blood is driven from the bleeding orifice. Ergot is therefore wholly contra-indicated in this, however useful it may be in some other forms of hemorrhage.

Purging and bleeding have for their object to reduce the bulk of the blood in general, and raising the head to diminish the amount within the cranium. In proportion as they are successful in accomplishing these objects they are, I suggest, hurtful rather than helpful to the patient. As we shall in all probability have to rely upon pressure in the end to stop the bleeding vessel, it is vastly better that this pressure be exerted by blood within the vessels than by blood extravasated into or upon the brain. The more blood in the intracranial vessels, the less room there will be for blood outside of them. I contend, therefore, that the correct treatment would be to place the head lower than the body and perhaps even to add to the cerebral congestion by the use of nitrite of amyl, which would at the same time diminish the *vis a tergo* in the injured vessel by its effect in lowering vascular tension.

Of course, the effect of these measures would be to bring on immediately the symptoms of pressure which otherwise might not have appeared until a few minutes or a few hours later. But in half an hour the escaped blood would have coagulated firmly at the point of rupture, the aneurismal sac would have filled with a clot, and the clot would have extended some distance back into the vessel. With the orifice thus effectually sealed the head might safely be raised, and the effect of the amyl allowed to pass off. We should then find the patient gradually emerging from his coma just at the time when, under the opposite treatment, the coma would be growing every moment more profound. Instead of a large clot, implying a corresponding degree of laceration of the brain, or compressing a corresponding area of brain-surface, we should have a relatively small clot with correspondingly little injury to the brain.

I admit that it would require some hardihood to carry out these measures in the face of the seeming aggravation of the symptoms which would immediately result, and that, in the event of a fatal termination of the case, the practitioner might be subjected to severe criticism. But, if the principle is correct, these considerations should not prevent its practical application.

In a case at the Presbyterian Hospital, a few weeks ago, in which I saw the patient within an hour after the hemiplegia occurred, I directed the pillow to be removed and the foot of the bed to be raised. Coma did not supervene, and I cannot be sure that the bleeding had not already ceased before the position was changed.

Cold to the head is indicated, not for the purpose of contracting the intracranial vessels, but because coagulation of the effused blood is favored by reduction of temperature, and it is upon the firmness of the coagulation that the safety of the patient will depend when the pressure within the cranium is reduced.

ON THE NATURE OF THE PHYSICAL PERFECTION OF MAN.

By L. HARRISON METTLER, A.M., M.D.,

LECTURER ON MENTAL AND NERVOUS DISEASES AND ELECTRO-THERAPEUTICS IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

In these days of biblical criticism much is being said about an antagonism between science and revelation. The development of life as taught by palæontology is accepted by some as an unanswerable argument against the verity of the Scriptures. According to our present knowledge, they say, man in the beginning could not have been created "perfect," with the perfection of the image of God. To escape the dilemma, many of the orthodox believe that the quality of primitive perfection is to be predicated of man's soul or spiritual essence only, and that, so far as his physical constitution is concerned, the disparaging dicta of science are absolutely true. The latter is in part our own view, but as the presence of the *anima* is the condition requisite to the progressive development of the organism as a whole, we believe that it is ever exerting a perfecting influence upon that organism in accord with its own perfect nature. Hence there is, as we believe and will endeavor to show, a certain perfection of the very highest sort attributable to the body of man, not only as it existed in the past but even more so as it exists in the present. Our knowledge of this perfection will increase with the growth of the study of philosophical anatomy.

Mr. Hubbell says: "Many common beliefs, such as the current one taught in our catechisms that man, some centuries ago, was perfect (without evil tendencies or maladies) overrules every logical palæontological induction and contradicts our experiences. The common assumption that bilateral symmetry prevails in the human organism precludes our recognition of the actual great disparities in correlative features. In truth, the factors of diversity (winds, light, nutrition, etc.) are not uniformly distributed, and hence the variations that are so conspicuous." Our author here runs the risk of assuming too much when he infers that man, "some centuries ago," could not possibly have been perfect in form, because at that time he was presumably subject to the same accidental influences which are transforming him now. The argument belongs to the *non sequitur* class, as the progenitors of both men and trees, for aught we know, may have been perfectly symmetrical when first they made their appearance upon the earth's surface. The variations produced by climate, nutrition, etc., never become established until after long periods of time. The present existing forms of life owe their difference, as compared with the primitive forms, to the cumulative force of heredity. This force is ever receiving, in the individual last in the line of descent, an additional impulse direct from the outer world; so that, as the development of the race proceeds. the power of heredity becomes stronger if the individuals continue to be surrounded always by the same natural influences. Yet even when these influences change as the result of migration or geologic transformation, the force of heredity continues to be cumulative, though now the accretions may be somewhat of a different sort and may become the origin of a new line of development. This, however, is always superimposed upon the old line but is never entirely substituted for it. Thus a wing is not a substitution for a fin, but merely a re-adaptation of the original part to accord with the altered modes of progression required by the altered media. Recognizing, then, the cumulative force of heredity, coupled with the long lapse of time required to produce the present actual disparities in the correlative features of man, it is not so very unreasonable to imagine that for a certain period of his primitive existence he may have been symmetrically perfect. This, of course, accepts the belief in the changeability of varieties but permanency of species. If, on the other hand, we assume that man is but the last link of that vital chain which reaches down to the very lowest forms of life—the protozoa—then we are compelled to admit that the forces of nature, coupled with those of heredity, must have commenced to operate long before his particular advent. Then man will possess only the merest tracings of that perfect symmetry which accompanied the beginnings only of all organic existence. The question of the correlation of species is still *sub judice*, but, however we may regard it, we will nevertheless see that there is an element of perfection in the physical constitution of man as in the forms of far lower and more primitive organisms.

Let us clearly understand, before proceeding further, what is meant by perfection. This attribute, as applied to the form of any object, admits of two conceptions. The one is absolute, and may be spoken of as a mathematical perfection. Thus a sphere and a cube are, in this sense, perfect; so also is any object endowed with such symmetry that portions of it relatively situated are exact counterparts. The other sort of perfection is always relative, and may be characterized as utilitarian. In this case the qualification rests upon the fact that the object fulfils exactly the purpose for which it was created. In outline it may be rough and irregular; yet, on account of that very roughness and irregularity, it is best fitted to accomplish its ends. Eccentric wheels, numerous appliances in the mechanical arts, the bones of the skeleton with all their excrescences, nodules, and roughened surfaces, are certainly perfect in perfectly accomplishing their purposes, though in regard to mathematical symmetry they are far otherwise. These two varieties of perfection, the æsthetic and utilitarian, are frequently met with in the same object; as, for instance, an ordinary cart-wheel. If we regard utility from the broad stand-point of whatever ministers to the pleasure, as well as comfort of man, then these two varieties of perfection are found most frequently combined in the realm of pure art. The artistic manufacturer combines the two when he adorns and beautifies the necessities of life. A simple statue or delicate scroll may have been carved for no other object than to please the eye. A rude four-walled house may have been erected for no other purpose than protection. A magnificent, highly ornamented palace, affording both protection and artistic pleasure, arouses in us the deepest sense of admiration on account of its beauty and utility.

In the physical structure of man we have the same two forces making toward perfection. From the study of embryology we learn that symmetry in the disposition of parts is the primal state of the human frame, and that the fœtus, were it excepted from all the influences of the outer world operating in a secondary manner through heredity, would grow in harmony with the demands of the most rigid mathematical ratios. Evolution, showing us man's susceptibility to variation in accordance with changing externalities, when added to the knowledge which has been acquired from embryology, might readily lead us to imagine that in the beginning of the race there did exist such symmetrically formed beings. But if it be true, as believed by many of the more advanced biologists, that man is simply the climax of an ascending scale of organized development here upon earth, we must look low down in the scale for the clearest evidence of the perfection of form, at a time when the influencing forces of external nature had only begun to operate.

Man is essentially an articulate; for, as Owen says: "A vertebrate may be defined as a clothed sum of segments. But in this highest province of the animal kingdom growth by repetition of parts rapidly gives place to the higher mode of development by their differentiation and correlation for definite acts and complex functions. Nevertheless, I am constrained to affirm, by evidence, that in the vertebrate, as in the invertebrate series, there is manifested a principle of development through polar relations working by repetition of acts and multiplication of like parts." Likewise is the testimony of Cuvier: "Tout être organisé forme un ensemble, un système unique et clos dont les parties se correspondent mutuellement et concourent à la même action définitive par une réaction réciproque. Aucune de ces parties ne peut changer sans que les autres changent aussi; et par conséquent chacune d'elles, prise séparément, indique et donne toutes les autres." Sir Isaac Newton expressed the same idea, though in doing so he did not realize it in its broadest aspect, when he declared that, "Similiter posita omnia in omnibus fere animalibus." The articulates, or homogangliates of Owen, are the first distinct manifestations of the active principle of "vegetative repetition" among the higher orders of animals. In the mollusks or heterogangliates this principle is not at once so apparent as in the articulates, which are above them; or in the radiates, which are below them and which lie upon the borderland between the animal and vegetable worlds. The bilateral symmetry of form, so universal among the articulated and vertebrated animals, is seldom found among the mollusks; yet that they are the connecting link between the symmetrical articulates and radiates is shown in the difficulty often experienced in separating their lowest representatives, the polyzoa or bizoa, from the zoöphytes, and in the marked resemblance which many of their highest representatives, the cephalopoda, bear to the true articulates. With this slight exception on the part of the mollusca, the principle of "vegetative repetition" witnessed in the articulata, of which the vertebrata, as stated above, are but higher examples, becomes more manifest the more we descend in the animal scale, until, finally, we reach a stage in which the individuals all possess regular geometric figures, such as the skeletons of the echini, star-fishes, etc.

Anyone who has extended his studies into the field of general biology, including, particularly, palæontology and comparative anatomy, must doubtless have been impressed with the remarkable similarity existing between the relative members of all the innumerable forms of animal creation. The fin, the wing, and the hand, the organs of locomotion are, in all essentials, identical. The organs of vegetative life, those specially concerned in the processes of waste and repair, such as the heart, lungs, alimentary canal with all its appendages, are singularly alike throughout the different species. The same is true of the centres of consciousness, with all their outlying projections of nerve and organs of special sense. What differences these all apparently do possess belong to their non-essential characteristics as parts of the organism, and are simply the results of the active principle of accommodation.

Let us draw our comparisons still closer and we will be surprised at the remarkable similarity existing between the relative parts of not only different animals of different species and of different animals of the same species, but even between the relative parts of the same animal. We may marvel that the wing of the bird, the fin of the fish, the forepaw of the quadruped, and the hand of man should all have the same anatomical structure; but our astonishment will be only the more increased when we learn of the structural similarity existing between the anterior and posterior extremities of all these creatures, between their shoulder and pelvic girdles, between their vertebral columns and skulls, between their various muscular systems, and between their ventral or anterior and their neural or posterior general cavities. Formerly these resemblances were spoken of simply as analogies. Later on, as the result of a further extended research, they were recognized as possessing a certain amount of mutual interdependence, and hence were characterized as homologies. Thus the humerus of the anterior extremity is homologous with the femur of the posterior, the basilar process of the occipital bone with the body of a vertebra, the laminæ and spinous processes of the vertebræ with the ribs and sternum, while all of these, again, are homologous with some higher and more perfect ideal, the homotype.

The bilateral symmetry of man, such as exists between the two hemispheres of the brain, the two lungs, the two sides of the heart, the two kidneys, etc., was known almost as early as that which exists between the two sides of the face, the two arms, the two legs. This sort of symmetry, though somewhat analogous to that of the homologous series, is yet something entirely different. Bilateral symmetry is what Aristotle and Newton referred to The symmetry of the homologous series is that intended by Cuvier and Owen. The former is not due to any reduplication of parts, but merely to collateral growth; the latter is a manifestation of the principle of reduplication and is dependent upon the articulated or segmented structure of the animal frame. Nevertheless, both bilateral symmetry and the symmetry of the homologous series are elements alike in the general æsthetic or geometrical perfection of the whole. Just as a solid ovoid or rhombohedron may have its diameters all of different lengths, yet, on account of their bearing certain precise relations to one another, we may say that the entire figure is geometrically perfect and harmonious.

We have thus far shown that the tendency in the physical development of all animals, when removed from all external influences, among which we must include those also operating through heredity, is toward a determinate geometrical form of some sort exhibiting a perfect symmetry between all of its correlated parts. Hence there is an ideal form of man, an archetype, from which the real forms are ever being diverted by the external forces of nature, over which the man himself has a limited amount of control in giving them variation by varying his own locality and mode of life.

The goal toward which morphology is urging—a science as far above that of human anatomy or comparative anatomy as the science of the political economist is above that of the mere statistician—is the definite form of this archetypal man. It owes its inspiration directly to the poet Goethe, who first conceived and wrought out the morphological form of plant-life. The notion of such an ideal man has been the source of not a little merriment to many of the self-styled practical men of science, as note, among many other instances, how the French Academy in 1808 ridiculed Dumeril for bringing forward his "vertèbre pensante," as they were then pleased to call it. If the assumption of an ideal type be an adequate means—yea, the very best means, according to our present knowledge—of explaining the uniformity in the appearance and development of man, we cannot see that such an assumption is any more preposterous than that of the principle of gravitation or of atomicity to solve the peculiar revolutions of the heavenly bodies or the strange phenomena of chemistry.

What, then, is the ideal form—the *Bedeutung*, as the Germans have it—of man? Simply a segmented bony column, sustaining, by means of certain bony arches which extend forward and backward, two cavities which contain the necessary organs for vegetative and conscious existence; the whole being enclosed by certain muscular plates for the purposes of support, protection, and mobility. This is the simplest expression of an essential vertebrate. The indefinite reduplication and regular succession of the following ideal vertebra of Owen will present to us a mental conception of the essential outline of the ideal form of man. As soon as the real form begins to deviate from this, we at once recognize the operation of the law of adaptation and selection.

The first appearance of the future being within the mass of cells composing the fecundated ovum is the so-called primitive streak. Immediately succeeding this, both in time and position, is the notochord, which occupies a line coincident with the centres of the bodies of the future adult vertebræ. Thus in the very beginning is raised the central pillar about which the entire superstructure of the adult being clings for support. Through an hereditary tendency impressed upon it by the demands of an increased mental development, one end of this pillar becomes greatly enlarged, the uppermost vertebræ composing the face and cranium. Depending upon the same hereditary impulse, and evoked likewise by certain special demands, the limbs make their appearance at four regular and determinate points of this segmented column. That the limbs belong to the plastic elements of the vital organization is proved by their entire absence in the murænа and anguis, the scapular arch alone here remaining, and by both limb and arch being wanting in the serpents and cyclostomous fishes (lamprey).

The brain or ganglionic centre for consciousness and volition, though never entirely absent where there is a nervous system at all with the power of voluntary motion, is nevertheless subject to very great variations. In the mollusks it usually consists of a single ganglion. In the articulates each segment is supplied with a separate ganglionic brain, though the most forward one of the chain—the one with which the organs of special sense are immediately connected—is sometimes spoken of as *the* brain. In some of the humblest representatives of this order a single segment, when severed from the rest, continues to grow and develop into another individual. It would therefore seem that the brain, so called, is not a portion of the nervous system conditioning existence, but rather an accommodation for a specialized function, for the nervous prerequisite to the vital phenomena evidently coextends with the entire chain. The higher we proceed in the animal scale the more comprehensive are the demands for intellectual and volitional phenomena; therefore the more imperative are they for the increased development of those specialized centres of the nervous system within which these phenomena take place. In man it appears that the encephalic mass (excepting the medulla, which is virtually an expanded part of the spinal cord proper) is this specialized portion of that central nervous system of which the cord itself is the primitive factor. Without the latter life is absolutely impossible, since within it reside the involuntary centres which control the vital organs. Destroy the former and we have loss of volition and consciousness, but not necessarily of life. This has been demonstrated by frequent experiment in pigeons and frogs, and occasionally by accident in man. Unlike the cord, therefore, of which it is merely an attachment added for the sake of a privileged form of neurility, the brain is capable of the most profound variations without impairment of the essential functions of vitality.

The projections from the brain, such as the olfactory, optic, and auditory nerves are also liable to great changes.

Of this fact there is ample illustration. So plastic' indeed, are these elements of the animal economy, that even in the same individual the loss of one will very materially affect the others. Everybody knows that the loss of one eye usually affects the other, while the loss of both sharpens the sense of smell and of hearing. Whether we attribute this result to a greater concentration of mental force or to a finer development of the remaining senses, the fact of the intensification of the perception indicative of cerebral differentiation remains the same. The blind fish inhabiting the waters of dark caves are also apt illustrations of the plasticity of these cerebral projections.

The fact that the brain is but a special development of a portion of the cord receives further support from the vertebrate theory of the skull. This theory, which asserts that the skull is nothing more nor less than certain vertebræ hyperdeveloped, is being rapidly adopted by all of the more advanced anatomists. Its proof depends upon the position, relations, and modes of development of the separate bones. The notochord of the vertebral column extends into the basilar process of the occipital bone, along the body of the sphenoid, as far forward as the vertical plate of the ethnoid. In the vicinity of the occipital condyles this line receives a sharper bend in man than in the lower animals, on account of this erect position. It constitutes, in a general way, the basal or central part of the skull. The remaining parts are made up of the superior or neural arches, consisting of the parietal, frontal, and squamous portions of the temporal and occipital bones; and of the inferior or hæmal arches, formed by the bones of the nose, the superior and inferior maxillæ, the two pterygoids, palatals, and mallei of the ear. These arches are believed to be respectively homologous with the laminæ and spinous processes and with the ribs and sternum of the trunk itself. In passing, we must note that the arrangement of these simple arches within the skull is rendered somewhat complex by the interposition of certain sense-capsules which have become ossified and permanently united to the surrounding osseous structures, such, for example, as the petrous part of the temporal bone; and also by certain extraneous investing bones, like the lachrymal, nasal, molar, etc., all of which are outside of the fundamental osseous structure of the head.

Having thus rapidly pointed out that the head is in reality an accommodating arrangement of one end of the spinal column, having a ventral and neural cavity, with their respective contents, located upon either side of a central pillar, just as we find in the rest of the body, let us now consider the homologous structures of the body itself. In the living anatomy the skeleton here consists of a certain number of vertebræ and ribs, re-enforced by the bones of the shoulder and pelvic girdles, of which we will speak more particularly when we come to examine the extremities. All the vertebræ, from the first cervical to the last coccygeal, have in the ideal their anterior and posterior arches, enclosing the ventral and neural cavities respectively. In the real, we find the posterior arches always present in the laminal and spinous processes, but the anterior ones, represented by the ribs proper, are apparently wanting in the region of the neck, abdomen, and pelvis. We say, apparently, because vestiges of them are still to be found in each of these localities. It will be remembered that the cervical vertebræ have each a foramen in the transverse process, and that the process itself has two ossific centres, one for each portion, in front and behind the foramen, respectively. That portion which is behind the foramen is the original transverse process, while that which is in front is all that is left of the primitive rib, now become ossified and permanently fixed to the vertebra itself. In a few instances a separate supernumerary rib, with its articulations all intact, has been found attached to the seventh, and even sixth, vertebra. In the lumbar region supernumerary ribs have also been discovered, but it is now generally admitted that the outer division of the large transverse processes of these vertebræ are the representatives of the true ribs. And, finally, the large lateral masses of the sacrum cannot be scientifically accounted for upon any other hypothesis than that they are the obliterated ribs which have here become ossified as a part of that bone and more or less firmly united to the proximal surface of the pelvic girdle—particularly of the ilium—instead of remaining free and movable as they are above, beneath the scapula of the shoulder-girdle. The demands for an increased mobility or fixation are sufficient to explain these slight variations occurring in the regions of the neck and abdomen, shoulder and pelvic girdles.

Now a word in regard to the appendages, and we will have completed the skeletal homologies. That the extremities are, indeed, mere appendages, and in no way intimately concerned in the essential vitality of the organism is established by their remarkable variability throughout the entire vertebrate order. Their relative positions and adaptable qualities are continually changing to meet the particular exigencies of the various forms of animal life. Existence is conceivable, even among the highest orders of animals, without their presence. As Owen says: "It is by no means essential to that organic type that it should be 'tetrapodal,' although it best accords with the force of attraction and other conditions of our globe, that not more *or less* [the italics are ours] than two pairs of the latent limbs or appendages of the vertebral segments should be developed to react as locomotor instruments upon its waters, its atmosphere, and its dry land." Oken regarded the limbs as "liberated ribs," but Owen has maintained, with a far better show of reasoning, that they are special developments of costal appendages and not ribs themselves. He believes, furthermore, that the scapulo-coracoid arch of the shoulder is the hæmal arch of the occipital vertebra of the head, and that, therefore, the arms of bipeds and the pectoral fins of fishes are parts of the head and not of the trunk. If the extremities be, indeed, mere appendages or hyperdevelopments of certain parts of the archetypal vertebra, they might theoretically appear anywhere along the vertebral series, and be as numerous as the vertebræ themselves. In some of the lower orders of animals—as, for instance, the myriapoda—in which the principle of segmentation is especially marked, this is amply illustrated. Geoffroy St. Hilaire, as well as some botanists, have remarked that multiple parts are extremely liable to vary in structure (Darwin), while Owen has shown that the degree of "vegetative repetition" bears a certain direct ratio to the lowered type of organization. Hence, in man, who belongs to the highest type, we can understand how the appendages, which originally were subject to the same principle of vegetative repetition, have now become associated with certain definite and determinate points along the vertebral column.

"The repetition of similar segments in a vertebral column, and of similar elements in a vertebral segment, is analogous to the repetition of similar crystals as the result of polarizing force in the growth of an inorganic body." This is the manifestation in the animal world of the principle of æsthetic regularity depending upon geometric ratios. In accordance with it, the symmetry of the limbs should exhibit itself longitudinally as well as bilaterally. In other words, all parts of the arm should have their counterparts in the leg. Such is the fact, the only difficulty in completely establishing it in nature being in some minor homologies between the shoulder and pelvic girdles. The similarity between the rest of the extremities is obvious enough. In studying these minor homologies we must remember that the erect position of man, as well as his slowly acquired but remarkable manual dexterity, have caused the arm and leg to make a turn of nearly a half-circle in opposite directions; so that the thumb and radial border of the former are relatively external to the body, while the great toe and tibial border of the latter are internal. In the embryo, however, both tibial and radial borders are preaxial, *i.e.*, turned toward the cephalic end of the spinal column. This explains why the extensor muscles of the leg happen to be anterior, while in the arm they are posterior.

Note the function, relative position, and mode of development of the os innominatum as compared with the scapulæ and clavicle regarded as one bone. How strikingly similar are the following parts: The spine of the scapula and the ilio-pectineal line of the innominate, the supraspinous fossa of the former and the sacral surface of the ilium, the infraspinous and iliac fossæ, the subscapular fossa and gluteal surface, the precoracoid bone—which is found only occasionally in man but always in the lower vertebrates—and the pubic bone, the coracoid process of the scapula and the ischium, the glenoid and cotyloid cavities! But enough has been said to show the identity of the four extremities.

Starting with the notochord, the very first appearance of the future being, we have now seen how the various parts of the entire skeleton, even those most dissimilar, are homologous with certain various parts of an ideal vertebra which in itself is the type of perfect symmetry. The skeleton is the foundation of the physical being, and if we can discern the elements of symmetry in the foundation we ought to be able to discern them in all those anatomical structures which are the outgrowth and sequence of the same. But now the problem becomes far more complex. For, as these structures partake simply of the character of aids in the production of the vital phenomena, and as their proficiency in the performance of their various functions is more or less dependent upon the nature of the surrounding world in which lie the immediate conditions for their activity, they are liable to far greater degrees of change and are hence occasionally discovered under the most profoundly varied forms. The digestive apparatus of herbivora and carnivora, the respiratory organs of aqueous and aerial breathing animals, the muscular systems of reptilia and mammalia are sufficient illustrations of this diversity of form. Yet, after all, these differences are more apparent than real, for they are not integral, but simply the result of an atrophy or hypertrophy of universally existing structures. In many of these structures the symmetry which accords with the symmetrical nature of the vertebrated type of skeleton is quite discernible. The bilateral symmetry of the respiratory, circulatory, and genito-urinary tracts is too manifest to require more than a passing notice; but in regard to the heart, the stomach, the liver, the spleen, and the extra right lobe of the lungs, there is a little more difficulty. Most of the anomalous conditions in the way of position and inherent asymmetry of these organs are clearly seen to be purely accidental when their embryological development is carefully studied. Originally the lobes of the liver were of equal size and extended for an equal distance on either side of the spinal column, growing out as diverticula from the fœtal midgut. The stomach was simply a dilatation of the continuous intestinal canal. As it went on enlarging it soon turned over upon its right side in such a way as to present toward the left the border which was at first connected with the vertebral column behind, thus carrying away from the median line the rudiments of the liver, pancreas, and spleen, which had already begun to be deposited upon the primitive intestinal tube (Quain). Similar explanations account for the irregularities found in the remaining viscera.

The homologous nature of the muscles of the extremities affords scarcely any more difficulty in its solution than did the osseous structures of these parts. But in regard to the great trunk-muscles, so extensive have been their variations in the human anatomy that now their original symmetrical simplicity seems to have become almost totally obliterated. Nevertheless, certain distinct groups, all possessing more or less similarity, can be quite accurately made out. In some of the lower vertebrates the deep fascia dips down from the surface toward the skeleton in four determinate lines. Two of these are median, constituting the hæmal and neural septa before and behind; and two are lateral, one on each side, extending in the direction of the transverse processes of the vertebræ. In fishes, and in some of the amphibia, the muscles exhibit an astonishing degree of segmentation, partitions spoken of as sclerotomes being inserted transversely across the walls of the trunk and corresponding in number and position with the vertebral segments. In man the same principle of muscular segmentation can be fairly distinguished, though here the modifications from the primitive type are very extensive, owing to the greater development of the limbs, which thus break into the continuity of the mural plates of the muscles of the trunk. Again, the simple primitive division of the muscles into *epaxial* and *hypaxial* is plainly portrayed in the adult human being; the latter being represented by the prevertebral muscles of the neck, together with the psoas and pyriformis, the former by the two great longitudinal masses of muscular tissue, characterized in morphology as the dorso-lateral and ventro-lateral muscles. To enter fully into this subject would require more than a separate essay, but enough illustration has doubtless been introduced to show that even the complex and intricate muscular system of man is subject to a strict principle of symmetry.

We have thus indicated in a few words the general symmetrical character of the human frame, though for want of space we have been obliged to mention only a few of its special features. We have seen how the vertebrate as a unit is simply a spinal column, having a ventral or nutrient cavity for organic life upon one side, a neural or psychological cavity for animal life upon the other, the rigid simplicity of this outline being modified by certain special developments, such as the enlargement of the head, the greater prominence of the anterior general cavity in comparison with the posterior, the projection of the four appendages, and a host of minor, but not less important variations, all of which are the resultants of the active principle of accommodation.

In man, therefore, we can plainly perceive the two operative forces of which we spoke in the beginning. The one is the supernatural, uncontrollable, primitive force which is ever tending to mould protoplasm after some definite archetype, whatever that may be. This force was ideally in existence before any appearance of protoplasmic matter whatever upon the face of the earth. In a word, it represents, as shown by its persistency throughout the entire animal kingdom, the preconceived idea of the Creator of that kingdom, and is hence in direct antagonism to any notions about a fortuitous origin of the same. It is the indelible stamp which He himself has impressed upon it, the line along which he has preordained that it should advance. It represents the elements of the perfection of symmetry, yet not in so rigid a manner as to preclude all future advantages of adaptation. The other force, on the contrary, instead of emanating immediately from above, and at a time previous to the appearance of matter, is dependent for its very existence upon the accidental influences of surrounding matter. This force is manifested in the law of natural selection and results in the survival of the fittest. It is discovered in the influences of climate, of modes of life, of civilization, of places of habitation. It is that force which renders the Esquimaux so different in stature, appearance, health, and mental capacity from the inhabitants of the temperate zone, and these, again, from those dwelling beneath the equator. It is a force largely under the control of the will of man, so far as his power of changing it goes, but one which nevertheless continues ever active in some mysterious way or another, regardless of his volition. It is a force which is forever fashioning the archetype into such forms as shall best adapt it to surrounding circumstances. It is thus a perfecting force, leading up to the perfection of adaptation.

A slight objection may be raised that man is then no more perfect than the lower animals in regard to these two elements of perfection, the archetypal or æsthetic and the adaptive or utilitarian. But as man is at the very summit of the animal kingdom, he necessarily represents the highest perfection resulting from the working together of these two forces in that kingdom. If in some particulars, such as strength or fleetness, he compares unfavorably with any animal, he makes it up and far outbalances it with others in which that animal is deficient. Add to this the fact of his acquired superior mental endowment, and it will be readily seen how vast are all his possibilities for future perfection. With these two powerful forces acting thus conjointly, the idea may not appear too entirely fantastic that their resultant, "some centuries" hence, if it could only be favored by universal proper hygienic conditions, would be an altogether perfect being, both mentally and physically.

> Then say not man's imperfect, Heaven in fault,
> Say, rather, man's as perfect as he ought;
> His knowledge measured to his state and place,
> His time a moment and a point his space.
> If to be perfect in a certain sphere
> What matter, soon or late, or here or there?—Pope.

1938 North Broad Street, Philadelphia.

OBSERVATIONS ON THE ETIOLOGY OF PNEUMONIA.

By THOMAS DARLINGTON, M.D.,

KINGSBRIDGE, N. Y.

The recent papers published on the subject of pneumonia, and the interest of the profession, as winter approaches, becoming more centred in the subject, have led me to give some of my experience as a country practitioner, and suggestions as to the cause or causes of the same.

Combined with a private practice, I have attended to the workmen on eight miles of the new Croton Aqueduct; and during the winter of 1886 alone, saw more than one hundred and fifty cases of pneumonia.

All of the workmen on the line were exposed to numerous causes predisposing to pulmonary disease. First, the tunnel was not well ventilated, and, as there were many workmen, the atmosphere became foul from their breath. Second, the kerosene-oil lamps in their hats smoked, and the mouth and fauces soon became covered with fine particles of carbon. Third, in the hard quartz-rock the steam drills produced a fine glistening powder which shone like diamond dust on the faces of the men as they came out. Fourth, from many crevices spring-water dripped constantly on their heads, shoulders, and chests. Fifth, poisonous gases were developed from the blasting of dynamite, and frequently so noxious were these gases that nearly a whole "shift" at once would be brought up asphyxiated. Sixth, from the warm tunnel (55° to 70° Fahr.), exposed to no drafts, the men would come up thinly clad, and wet with the drippings from the roof and perspiration, in mid-winter, to the surface, where the wind blew and the temperature was more frequently below 15° than above it. Nearly all were intemperate, few properly clad, and many had improper and insufficient diet.

All of the cases to which I refer were intra-alveolar (lobar) pneumonia. There were many cases, undoubtedly, of interstitial inflammation, but these are not included in the above. Most of the cases were removed to some city hospital on the evening of the third, or by the morning of the fifth, day of the disease, therefore I cannot give much information as to the treatment or mortality, but can speak specifically only as to the cause, except in about twenty of the cases which I kept through the disease.

At different shafts the disease manifested itself by different symptoms. There seemed to be no particular difference in the number of cases by changes in the weather, whether muggy and warm with an easterly wind, or very cold, clear, and blustering, with a westerly wind, except in sporadic cases, which occurred principally in the very cold winter weather.

At Shaft 23, in February, I had twenty-five cases in ten days. In these cases the symptoms were practically uniform. All of them commenced with a chill, more or less severe, followed by a temperature from 101° to 104°. There was also slight jaundice, vomiting, spasmodic cough, some diarrhœa or dysentery, no delirium, but frontal headache, sweating—though in a few cases a dry skin—an absence of, or very little bile in the passages, which were extremely fetid in character. The patients complained but little of pain. The sputa was of various colors; it was in most cases of a light rust color preceded by jet-black sputa, composed principally of carbon from the lamps; and in some cases it continued to be more or less so colored to the end of the disease. In all of the cases there were symptoms referable to the liver, but whether these were due to previous alcoholism, or to the disease itself, I was unable to determine. Besides these symptoms there was also generally scanty urine. The vomiting was constant, and in most cases seemed to be watery material from the stomach. This epidemic occurred in one room of a large shanty in which eighty men slept, forty during the day and forty in the night. There were but two windows, and these were never open. The odor was that of a menagerie. The sputa and vomited materials went on the floor; these were covered with ashes or dirt and swept up. On the tenth day I had the room emptied, the sides and ceiling whitewashed, the bedsteads washed, the bedclothes and mattresses taken out into the sunlight and as much as possible washed, the windows opened, and the floor sprinkled with chloride of lime. Then the epidemic as such ceased abruptly. After this cases occasionally occurred in this room, and in an annex building, where four or five occurred at once; but the same disinfecting and fresh-air treatment accomplished the same result. Some of the shanties in the neighborhood, particularly the darkies' quarters, became infected in the same manner.

At Shaft 24, the disease seemed to take a different type. There was little vomiting, no diarrhœa or dysentery, no sweating or jaundice, simply hepatization, dyspnœa, and symptoms of fever. Here there was no overcrowding in the boarding-houses, not so much smoke in the tunnel, and no water. Here, however, the rock was very hard and flinty in character, and the atmosphere in the tunnel was charged with fine particles of quartz. In these cases the predisposing, if not the exciting, cause was due to these.

At Shaft 20, the cases assumed still another type. These were largely among Italians. But few of these went to the hospital. Nearly all commenced with symptoms of pleurisy, and by the second or third day the inflammation extended by contiguity to the lung-tissue itself. Many of these men worked on the surface, and were often exposed to an icy wind that had a sweep for miles. Here also it was quite wet, and rheumatism was common.

The cause here seemed to be rheumatic, or prolonged exposure to cold. All of these cases made good recoveries. The shanties for the Italians were not as well built as for the other workmen, and to this I attribute partly the good results obtained. It was possible to see the daylight from the inside in any portion of the building, so that there was no lack of fresh air.

In a few isolated cases the disease evidently originated from injuries received to the chest. These cases involved invariably one lobe of the lung only.

In other cases the disease occurred immediately after intoxication and exposure all night on the ground.

In all of the cases the cough was peculiar and not entirely due to the pneumonia, but came from a neurosis or irritation of the pneumogastric nerve from poisoning of the gases set free in the explosion of dynamite. It was spasmodic in character and similar to a malarial cough or pertussis.

In some cases fatigue seemed to be either exciting or predisposing cause; which, I could not say.

Is pneumonia the manifestation of a systemic disease with a characteristic local lesion? or is it a purely local disturbance with constitutional symptoms? My experience leads me to say both. Looking at it in the epidemic form, and taking into consideration the fetid character of the passages, the diarrhœa, and symptoms referable to the liver, it seems to me that in some cases it is a systemic disease, while in other cases it certainly is not.

In the infectious cases the stage of incubation did not seem to be over forty-eight hours. Had the character of the discharges from the bowels anything to do with the pneumonia? Did these occur from, or were they assisted in occurring, by the damming back of the portal system? or conversely? Certain I am that purgatives, particularly those of an antiseptic variety, such as mercury, used early in the disease, seemed to modify the course and symptoms greatly.

In regard to the treatment, I believe the less treatment the better. I never used aconite but once, and on that occasion the patient drank it all in one dose. And I did not give whiskey, for it would have disappeared immediately. I feel convinced that if we do not give much aconite, we will not have to use so much whiskey. And I firmly believe that whiskey, as a rule, should not be given, and that if a stimulant must be had, opium, in the form of Dover's powder, is much better. I made no selection of the cases that I kept, they were simply those who would not go to the hospital; but nevertheless I did not have a single death from pneumonia on the line. My treatment simply consisted of cathartics (principally pil. cath. co.), ammonia muriate with ipecac, and last, and of most importance, *fresh air.*

DR. SANDS AND THE NEW YORK PATHOLOGICAL SOCIETY,

By JOHN C. PETERS, M.D.,

NEW YORK.

Dr. Henry Berton Sands was born in 1830, and died, very suddenly, on November 18, 1888. He joined the New York Pathological Society in 1857, when he was twenty-seven years of age, and in less than nine years was elected its President, when he was only thirty-six years of age. He remained a most highly esteemed member for thirty-one years, or until the last day of his honorable and eventful life.

On his entrance into this Society he was thrown into emulation with those grand and scientific workers (who were then in their very prime), Alonzo Clark, Willard Parker, William H. Van Buren, C. E. Isaacs, John C. Dalton, E. R. Peaslee, Robert Watts, John Watson, Gurdon Buck, Gustavus A. Sabine, Louis A. Sayre, George F. Shrady, Fordyce Barker, Ernst Krakowizer, Cornelius Agnew, John W. S. Gouley, George T. Elliott, John T. Metcalfe, A. C. Post, James R. Wood, Louis Bauer, Daniel Ayres, Henry B. Noyes, John C. Draper, T. G. Thomas, Edward Delafield, William H. Draper, F. S. Thebaud, James R. Leaming, William Detmold, Dr. Voss Henschel, Thomas M. Markoe, Abraham Jacobi, and scores of others, and they soon made Dr. Sands their President. Of our long line of illustrious Presidents, sixteen have gone down to their graves. Some have been slowly and gently led there by old age, notably Alonzo Clark, Willard Parker, William H. Van Buren, Alfred C. Post, Gurdon Buck, James R. Wood, and Joseph Hutchinson.

More have been suddenly cut off in the very midst of their usefulness, especially John A. Swett, Charles E. Isaacs, Robert Watts, Edward R. Peaslee, Erskine Mason, and Henry B. Sands. None died so suddenly or more lamented than Dr. Sands. None showed more fully the inestimable value of a good and honorable life and its true nobility. He always had many worthy rivals, few equals, and no superiors.

When Dr. Sands joined this Society he seemed determined to become a great pathologist rather than an eminent surgeon, and appeared to be working with the microscope almost as much as with the scalpel. The first twenty of his specimens were all of cancer, sarcoma, or other malignant or allied diseases. The only exceptions were an hydatid cyst of the neck with echinococcus hooks, a case of hip-disease, a melon-seed in the trachea, diphtheria confined to the larynx, aneurism of the gastro-epiploic artery, and an iron bullet in the omentum. His list of cancers included some of the breast, tibia, lip, knee, stomach, small intestines, ovaries, arm, inguinal glands, rectum, liver, spine, brain, duodenum, heart, uterus, etc. All these came from different subjects, but, finally, he found one which contained such a complete pathological museum of cancer that he deeply regretted that the usages of this Society and the regulations of Bellevue Hospital did not permit his bringing the whole body.

He brought gross and microscopical drawings of his cases, andh is principal discourses were of round, oval, spindle, caudate, and other cells; of fibro-plastic, recurrent, fibroid, epithelial, and other tumors. But in 1860 he became the partner of that great, genial, and ready surgeon, Willard Parker, and gradually dropped more and more into operative surgery. From that time on his operations became countless, and no one was ever done in a slovenly way or rash manner. Dr. Sands pursued no study or science further than it was practically useful to himself and his patients, and although he always kept up his familiarity with the microscope, he soon left its wonders mainly to those who devote themselves exclusively to its mysteries. He devised very few new operations, but not many days ever passed after one was heralded before he would be doing it with a dexterity and perfection which might well make the originator envious. Yet he was also very conservative, for he never totally abandoned an old and well-tried method until he was fully convinced that the new was superior. Good judgment always went hand in hand with his most progressive and aggressive surgery, and he ever showed that great business capacity is not incompatible with delicacy and tenderness of mind.

He was always highly respected by all his colleagues, and was often their mainstay in counsel. But he was the greatest favorite with the public.

Hundreds of grateful patients and enthusiastic family physicians made him their surgical idol, and still delight to recall instances of his great skill and kindness. They dwell upon the delicacy of his touch, the quickness and thoroughness of his work, the sharpness of his knives, and the niceness of his stitches, the brightness of his eye, the clearness of his glasses, the geniality and hopefulness of his manner, the compactness and alertness of his person, the neatness of his dress, the perfection of his hands, and even the smallness of his boots; but above all the pleasantness of his ways. His presence in the sick room brought no terrors, for everyone knew he would inflict no pain that science could prevent, and run no risk that skill could avoid. His bright smile and friendly nod from his carriage window were eagerly looked for; the rattle of his wheels seemed to carry hope; the vigorous slam of his carriage-door gave new confidence; and his rapid steps brought assurance that a skilled friend was quickly bringing help; while his cheerful and confident entrance into the operating-room appeared to prove that all that the brain of man could devise or the hand of man execute would be put forth for the welfare of his patients. He never left a house without leaving hope or courage or both behind. Yet he was one of the most frank and truthful of men. His religious friends maintain that he was endowed with all that was most manly and lovable in the Christian character; that his great capabilities were always watched by an overruling providence, the traces of which were even evident in some of the incidents of his fearfully sudden death. His helpless body was not left to the indignities, shameless curiosity, and savagery which so often attends instantaneous death in the streets, but was carefully sustained in the arms of a devoted friend. It was driven rapidly to his handsome home, where scores of friends, assembled to greet him with music and rejoicing, instantly became the strong comforters of his desolate family.

They tell us to believe that his soul was borne swiftly upward as in a heavenly chariot, and was welcomed with celestial music and rejoicing. They bade us

> "Hark to the bursts of acclamation :
> And hark to the loud triumphant chords."

The more superstitious point to the texts of his birthday and death-day : "I come as a thief in the night ;" "In a moment thou shalt die."

The Pagans say that his mercifully swift cutting-off reminds them of the fate of Æsculapius, the first great physician, and of Chiron, the first great surgeon. They both died young, and are said to have been slain by the thunderbolts of Jupiter, because they saved too many lives and raised too many from the dead. But in recognition of their virtues he translated one into the magnificent constellation of Orion, and the other into that of the Centaur.

> "Let the old Heathens tune their song,
> Of great Diana and of Jove.
> My thoughts surmount these lower skies,
> And look within the veil."
>
> "With glory clad, with strength arrayed,
> The Lord o'er all nature reigns ;
> The world's foundations he strongly laid,
> And the vast fabric still sustains."

Progress of Medical Science.

Eruptions of the Skin occurring during the course of Malaria.—Dr. Retiwzew has made an analysis of the cutaneous eruptions observed by him as occurring during the course of intermittent fever, in two thousand cases of the latter disease. 1. Roseola, which differed from typhus roseola in the fact that it very seldom became petechial, was seen in 2.5 per cent. of all cases. 2. A large macular form of erythema, which was localized principally upon the extremities, occurred in three per cent. Sometimes this erythema involved the whole surface of the body, and it was attended with itching and burning sensations. Occasionally a hemorrhagic form of erythema was seen. 3. Urticaria occurred in 45 (4.5 ?) per cent. of all cases and soon disappeared. It was sometimes combined with erythema, but a hemorrhagic form was not observed. 4. Herpes facialis was quite frequent, being noted in twenty-two per cent. of the cases. In one instance the author met with an herpetic eruption upon the palms of the hands and forearms, combined with purpura of the lower extremities. 5. Herpes zoster was seen in only one case. 6. Miliaria was encountered, but evidently was merely an accidental complication due to profuse perspiration. 7. The most common eruptions met with during the course of malaria were primary purpuric spots, purpura simplex ; and hemorrhages, which were usually complications of the severer forms ofn intermittet fever. These petechiæ were usually situated upon the chest, abdomen, and inner sides of the thighs, occasionally spreading over the whole body.—*The Boston Medical and Surgical Journal*, November 22, 1888.

The Prognosis of Carcinoma after Surgical Interference.—Professor König has called attention to the fact that the risk to life from operations for the removal of cancer is steadily diminishing, owing to progressive improvement of the technique. The most important question now is, whether we stand in a position through operative measures to cure carcinoma. Speaking with strict scientific accuracy. "cure" would mean that after a long series of years not only would there be not the slightest return of the disease at the seat of operation, but also none elsewhere, as metastatic or glandular carcinoma. Practically, however, for both the surgeon and patient "temporary" cure is an important question. If the latter can be freed from a painful disease two, three, or four years and his life prolonged for a portion of that time, an important service is rendered him. At the Göttingen Clinic, of 66 cases of return of the disease after operations for cancer of the breast, nearly half recurred during the first six months, and another third, making 52, during the second six months. Of the remaining 14, the return occurred in 7 at the end of the second year ; in 4 at the end of the third year ; in 2 during the fourth year, and in 1 as late as ten and a half years. Of 77 cancers of the rectum, 60 were operated upon by removal of the diseased bowel ; 16 with extirpation of the anus and a portion of the rectum ; 44 with resection of the rectum but retention of the anus. The peritoneum was opened 15 times, but in only one case did suppurative peritonitis result. Much importance was attached to the preliminary preparation of the patient by diet, emptying the bowels, etc. Eighteen per cent. of the patients remained cured for more than three years ; ten per cent. for more than two years. Of 4 patients upon whom extirpation was practised, 1 had a stricture ; not one had continence of fæces. Of 17 operated on by resection, 2 had stricture ; 9 incontinence ; 6 were able to retain the fæces. The author thinks theser esults not very encouraging, and recommends colotomy as a palliative measure in cases of rectal cancer that cannot be operated upon.—*The American Journal of the Medical Sciences*, December, 1888.

Wound of the Cervical Sympathetic.—Dr. Israel has described a case of excision of a cervical tumor, in which symptoms of paralysis of the sympathetic were observed after the operation. A man fifty-seven years of age was suffering from a large cancerous growth, involving the glands of the neck. After the large vessels and pneumogastric nerve had been carefully separated from the growth, it was found to be impossible to entirely free the sympathetic, and a considerable piece of it was excised. The patient recovered from the operation, but the moment after its performance the following symptoms were observable : Contraction of the pupil and diminution of the ocular aperture, followed the next day by redness of the ear and corresponding side of the face, and considerable swelling of the corresponding side of the tongue. The pulse was not affected.—*Centralblatt für Chirurgie.*

Primary Purulent Pericarditis.—A fatal case of primary purulent pericarditis is reported by Dr. Foureur. The patient was a woman, aged thirty-eight, in the Hôpital Saint-Antoine, in Paris. She was in excellent health till within a week of her death. There was sudden onset of epigastric pain and dyspnœa, and on the day when she came into the hospital, fever ; temperature, 104° F. ; pulse, 120 ; heart sounds distant ; no friction audible. The heart's action rapidly failed, and after some attacks of fainting she died on the sixth day. The autopsy showed great distention of the pericardium with nearly a pint of greenish pus of slightly fetid odor, in which was floating much false membrane. There was no tubercle anywhere, and no pleural effusion. A careful examination of all the organs failed to show any other focus of suppuration or disease to which the purulent pericarditis could be considered secondary. In the blood no bacteria could be found either by the microscope or by methods of cultivation, and no bad results followed its injection into rabbits and guinea-pigs. In the pus the streptococcus pyogenes was easily diagnosed by the microscope, and the same was abundantly demonstrated by cultivation, and further by the inoculation of the fresh pus into a rabbit and a guinea-pig, with rapidly fatal results. After four generations of artificial cultivation, however, the streptococcus lost its virulence, a point characteristic of the streptococcus pyogenes, and its inoculation was followed by trifling local abscesses. —*Revue de Médecine.*

TREPHINING THE STERNUM FOR PUS IN THE MEDIASTINUM.—At a meeting of the Medical Society of London, recently (*The Lancet*), Mr. Charles A. Ballance read a paper on a case in which the gladiolus sterni was trephined for pus pent up in the anterior mediastinum. The patient, aged thirty-five, was admitted into St. Thomas's Home on August 31, 1887, complaining of a discharging abscess over the front of the upper part of the chest, accompanied by constant and severe pain, and great tenderness along the breast-bone; also of fever, anorexia, loss of strength, and want of sleep. There was a history of inflammation of the lungs two years before; for three months there had been mid-sternal pain, and a lump had formed, into which an incision had been made and much pus evacuated. This was followed by a discharging sinus which, on admission, was found to lead down to bare bone at the left second costo-sternal articulation, and the probe could be passed still farther into a space behind the gladiolus. The sternum itself was acutely tender on palpation, and was the seat of constant dull, aching pain. Another swelling had formed over the left fourth, fifth, and sixth costal cartilages, and the discharge from the old sinus was less copious than usual. Two days after admission the lower swelling was incised, and the old sinus laid freely open. During the next five days rigors occurred, and it was decided to explore behind the sternum for pent-up pus. Two trephine-holes were made, and the intervening portion of bone cut away with forceps. The bone removed was found permeated by pus, and on looking into the anterior mediastinum a layer of thick creamy pus was seen on the front of the pericardium; this was carefully syringed away, and much carious bone was then scraped by means of a Volkmann's spoon from behind the sternum. Finally the wound was irrigated with sublimate lotion, packed with wet sublimate dressing, and covered with a dry dressing of the same character externally. The patient made a rapid and complete recovery, the sternal opening becoming filled in by fibrous tissue. Mr. Ballance was not aware of any case in which treatment had been applied to the posterior surface of the gladiolus. He took it from the first that the illness of the patient two years before had been puerperal or septic in origin, and had left some focus of disease in the interpleural space. By scraping the posterior surface of the gladiolus he could not hope to eradicate all the germs of the disease, and the completely successful issue of the case was, he thought, in no small degree due to the constant association of the diseased surfaces during convalescence with corrosive sublimate. The sternum had been trephined for abscess or foreign body in the mediastinum, for paracentesis pericardii, and the operation had been suggested in order to facilitate the ligation of the innominate artery. The two most prominent symptoms of mediastinal suppuration appeared to be dyspnœa and constant severe pain. A carefully compiled list of published cases of mediastinal suppuration accompanied the paper. In the discussion of this paper, Mr. M. Sheild said that he had twice seen pyæmic abscesses perforating the sternum and giving rise to pulsating swelling. They followed acute necrosis; both were opened, and both terminated favorably.

SUPPURATIVE OVARIAN TUMOR CURED AFTER SPONTANEOUS RUPTURE.—In the *Sei-I-Kwai Medical Journal*, of Tokio, Dr. Kawahara reports a case of ovarian tumor in which suppuration and spontaneous rupture through the abdominal walls finally resulted in the cure of the patient. The history of the case was one of gradual tumor-formation after childbirth. Paracentesis was done several times to relieve urgent symptoms. The last time the patient was tapped an offensive dark brown fluid was removed. A little later an ulcer appeared at the site of the last puncture. This began to discharge pus, the patient growing weaker and becoming more emaciated all the time. In the beginning of July pain occurred suddenly in the umbilical region, and the patient was in great distress. On examining the umbilical region it was found to have swelled up in the form of a globe, and to be of a red color. When pressed, great pain was felt and there was also fluctuation. The middle part seemed almost ready to break. The patient was advised to have the part opened, but did not give her consent. Besides, as she was thought to be in danger from being very much emaciated, it was not insisted upon, anodynes and tonics only being ordered. After a lapse of a week, however, the umbilical region suddenly gave away, and thick pus flowed out, the offensive smell of which was almost unbearable. At this time pain was extreme in all parts of the abdomen. Coldness and rigors came on, accompanied by fever. On examining the abdomen three ulcers were found—one in the umbilical region, already broken, which when pressed poured out fetid pus. The other two were the wounds made by paracentesis below the navel, which were almost ready to give way. Under antiseptic irrigation of the wounds and pus-cavity the patient began to mend, and finally made a good recovery. The author appears to think that there was no doubt concerning the ovarian nature of the tumor.

THE VALUE OF POSTURE IN LABORS.—Dr. Rubio, in a paper read before the recent Spanish Gynecological Congress, laid great stress upon the important part that the posture of the patient plays during labor, both physiological and abnormal. (*The Lancet*). During the first stage, he merely keeps the patient from going from one room to another, to avoid catching cold. During the expulsive stage, though he prefers the supine, or, at least, a horizontal position, as a rule, he changes it to a sitting posture where there is asthma or cardiac weakness, also where the pains have become inert through uterine fatigue. Where there is any version of the uterus, it is necessary to pay due regard to its direction. Thus, if there is anteversion, the patient should be placed on her back; if there is lateral version, she should lie on the side opposite that to which the fundus uteri is inclined, so as to bring the fœtal axis to coincide as nearly as possible with that of the pelvis. It is, of course, a recognized fact that a change of posture will frequently facilitate the descent of the head even when there is no abnormality either in the position of the child or of the direction of the uterine axis. When the fœtal position is transverse, the patient should be laid on the side opposite to that occupied by the head, with a pillow under the abdomen. The adoption of the genupectoral position has frequently been found of service by Dr. Rubio. When there is prolapse of the cord, and it is being dragged upon in a dangerous manner, he raises it above the head, and keeps it there during several pains, the woman being placed in the genupectoral position. Again, in complicated presentations, he has found this the best posture for their reduction, and in arm-and-shoulder presentations, where the amniotic liquid has escaped, and the practitioner in attendance has been unable to insert his hand and turn, Dr. Rubio, by the adoption of this position, has found it possible to execute the necessary manœuvre.

THE following general antidote for poison is given in the *American Journal of Pharmacy*: Equal parts of calcined magnesia, wood charcoal, and hydrated oxide of iron, with a sufficient quantity of water. This is a harmless and simple remedy, applicable in cases in which the poison is unknown.

FOR the removal of an obstinate pelvic cellulitic mass, the editor of the Cincinnati *Lancet-Clinic* states that the following prescription proved unexpectedly efficacious:

℞. Extract. belladonnæ,
Camphoræ pulv. . . . . .āā ʒ j.
Unguent. hydrargyri. . . . . ℥ ss.
Lanolin. . . . . ℥ j.

M. Sig.—Apply to the skin over the swelling, on Canton flannel.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, December 8, 1888.

THE TREATMENT OF PNEUMONIA.

It is commonly believed that pneumonia is attended at the present day with an ever-increasing mortality, though we do not know that this belief rests upon any surer foundation than the sum of individual impressions. But whether the fatality of the disease be greater than it was in former years or not, certain it is that the results of the treatment or, more correctly speaking, the management of the affection at the present day are far from satisfactory. The mortality, whether relatively greater than in years past or not, is very high, as high in fact as to constitute a reproach to medical science.

At the first Congress of the Italian Society of Internal Medicine, held recently in Rome, Dr. Maragliano, of Genoa, took this subject as the theme of his address (*La Riforma Medica*, October 30, 1888). He began with the assumption, now pretty generally admitted, we believe, that the disease is infectious in its nature, depending upon the presence of a specific micro-organism. The local inflammatory process in the lung is due, he maintains, to the presence of the micro-organisms, while the general symptoms are the result of the pouring out into the blood of the poisonous material eliminated by them. Lucatello has shown that the injection of sterilized blood-serum, withdrawn from a patient suffering with pneumonia, induced pyrexia, while the injection of blood from the same patient, after his recovery, gave rise to no symptoms whatever. The one symptom in pneumonia which causes the greatest anxiety, since it indicates the chief danger to the patient, is the rapid pulse. This disturbed action of the heart has been attributed by Jürgensen to the increased labor thrown upon the organ and to nutritive changes in the myocardium resulting from the high temperature. Maragliano, however, regards these as merely accessary cases, and believes that the condition is due primarily to the presence in the blood of some toxic material. The cardiac disturbance occurs too early in the course of the disease to be satisfactorily accounted for by Jürgensen's theory, and, furthermore, it has been shown experimentally that the blood of a pneumonic patient does exercise a marked toxic effect upon the heart muscle.

The disease is a self-limited one, it is true, but should the treatment be, on that account, purely expectant? It should not, the author maintains, for daily experience shows that the patient's life may be extinguished before the fires of the disease die down. The ideal indication is, starting with the assumption of a specific infection, to destroy this infective material, but, failing in this, every effort should be made to remove as fully as possible from the circulation the products of this infection, to purify the blood from the toxic material contained in it.

The first of these indications cannot, the author holds, be satisfactorily met. The attempts made to destroy the micro-organism by parenchymatous injections of antiseptic substances into the lung have not given results commensurate with the hopes of those who have undertaken them. Lépine, indeed, claims to have derived great advantage from this method, but Maragliano has never seen any good results in the cases in which he has employed this method, although he says he has never seen any harm so caused. Mercurial inunctions and the internal administration of calomel, potassium iodide, and other substances, have likewise, in his experience, been barren of results.

It remains, therefore, to promote elimination of the toxic matters from the blood. Among the first of the methods having this aim in view is blood-letting. This measure was formerly in vogue to combat the local inflammatory process, and, being found inefficacious in this respect, was abandoned. But now it is proposed to revive it on more rational grounds, as a means of removing from the system a certain amount of the poisonous material at a critical time, when the heart is on the point of being overpowered, and thus enabling it to hold out a little longer until the production of fresh poison has ceased and the old has been eliminated through the normal channels. The author himself bled twelve cases of pneumonia of average gravity, abstracting from five to ten ounces on the fourth or fifth day of the disease, the venesection being repeated once, and in one case twice. He found no change in the temperature or in the local morbid process following this operation, but there was an improvement in the condition of the circulation. The pulse was diminished in frequency and became fuller, and the amount of urine was increased. The twelve patients recovered. The author while speaking with some reserve, as most people do at the present day in respect to blood-letting, nevertheless ventures to affirm that the procedure, when done intelligently and in response to plain indications, will do no harm and may even render good service. It should not be forgotten, he says, that in a disease like pneumonia we must act promptly, and must look to the averting of immediate danger. When it is remembered that it is a question of one day or, maybe, part of a day, and if we can tide the patient over that time he will recover, it will be seen that we have to occupy ourselves with the present and not with the future.

It is believed by some that increased diuresis also aids in removing the toxic agent from the blood, but the author was unable to satisfy himself, by experiment, that elimination occurred in this way. He believes, however, that the sweat carries it off in a measure; hence the increased diaphoresis which is present should not be repressed.

The fever is often a source of danger by reason of its unfavorable influence upon the heart, and it should therefore be combated when it reaches a dangerous point. The danger from a high temperature in pneumonia cannot, the author holds, be judged accurately by the thermometer, but by its effects in the individual case. The means which he favors for reducing temperature is the graduated bath, and he does not fear any evil consequences from its intelligent employment.

Lastly, the heart itself usually calls for help, and its appeal must not be allowed to pass unheeded. In order to sustain the strength of the organ attention must be paid to the diet, which should be as generous as the patient can stand. Alcohol should be used freely, not only after cardiac debility has become manifest, but also as a prophylactic. It need not, however, be given in very large doses, a teaspoonful of brandy every hour being ordinarily sufficient. To sustain the organ when it has begun to flag, preference is given to digitalis, though when rapid action is necessary strophanthus may be very useful. Bloodletting here also may be of great service in relieving mechanically the pressure upon the right heart.

This, in brief, is the plan of treatment which Dr. Maragliano has found most satisfactory in pneumonia, and it is practically a plea for bloodletting. It is true, he advocates it somewhat timidly, and takes pains to declare that he is not a bleeder; nevertheless, he urges its employment in certain cases, when the heart is on the point of laying down its burden, and he believes that its judicious employment may save many lives that otherwise would be sacrificed.

THE DRUGS THAT LIVE.

The public hospitals, dispensaries, and prisons of Paris are all supplied with drugs through the Pharmacie Centrale. Consequently the records of this establishment show the changes in the amount and kind of drugs that take place in pursuance with the progress or vagaries of modern therapeutics. MM. Bourgoni and Beurmann have studied these records of the past ten years and give some interesting facts derived therefrom. The increase in the use of antiseptics is most striking, as shown in kilograms, as follows:

	1876.	1880.	1885.
Carbolic acid	369	2,876	11,217
Corrosive sublimate	102	197	314
Iodoform	22	84	353
Salicylate of soda	0	324	353

On the other hand, the following drugs either did not increase, or fell off in amount very much: Salicylic acid, salicylate of bismuth, thymol, and permanganate of potash. As for other drugs, subnitrate of bismuth increased from 347 to 419 kilos.

Quinine increased from 47.290 to 70, but has fallen off of late, while the minor alkaloids, cinchonin and quinquina, seem to be very much more popular than they are in this country.

The amount of iron sold is on the whole about the same. Of the various preparations the ferro-potassic tartrate and the sirup of the iodide increased in amount, while the chlorides and iodides decreased. Arsenic, in almost all its forms, was dispensed in increasing amounts every year, and is a drug evidently growing in popularity in Paris.

The consumption of purgatives of various kinds was remarkably constant, both absolutely and relatively to each other. Furthermore, the amounts varied little from those sold in the previous decades. So that the eleemosynary purgation of Paris seems to take place under certain very definite laws. The favorite purge is castor-oil, of which over 3,000 kilos are taken yearly, which is equal to about 180,000 doses. Next in favor comes sulphate of magnesia, of which about 2,500 kilos, or 150,000 doses, are taken yearly. Third in the list is sulphate of soda, of which the yearly consumption is about 1,500 kilos. Calcined magnesia, rhubarb, purgative salts *en bloc*, manna, senna, aloes, jalap, and scammony follow, croton-oil standing lowest in actual amount.

It would not be far from the truth to say that for the past twenty years the yearly free purgations have averaged half a million; the various salines, castor-oil, aloes, senna, rhubarb, and croton-oil being the chief agents.

Leeching has fallen off about one-half, the number of leeches sold in 1876 being 50,650; in 1885, 26,320.

The amount of alcohol consumed increased up to 1880, but since then has decreased. The consumption of caffein has increased greatly, but not that of tea or coffee.

Relatively the increase of chloroform sold in 1885 was greater than that of ether.

Chloral increased from 351 to 842; of the three bromides—potassic, sodic, and ammonic—the potassium salt increased most, and the ammonium salt next, while the former is still used vastly more than any other, perhaps because it is cheaper. Opium preparations do not show much change, except that codeïa has become very popular, while narcine has fallen into disuse.

USELESS DISPENSARIES.

Our Brooklyn neighbors are beginning to feel the inroads made upon the doctor's practice by the excessive accumulation of free dispensaries in that city. Dr. Emmett D. Page, writing in the *Brooklyn Medical Journal*, discusses the subject with a great deal of emphasis. At the present time, he says, there are in Brooklyn twenty-three dispensaries, with rumors of three more soon to be started. These institutions each treat from 5,000 to 30,000 patients annually.

He adds: "In these dispensaries are about one hundred and fifty physicians. Their yearly work will average from $1,500 to $5,000 at regular office charges, which would make a yearly gift of $300.000 to $500,000. One high in the practice of medicine here in this city has estimated that in the hospitals and dispensaries of this city alone there is donated free to the inhabitants of the city yearly upward of $1,000,000, and this without any extra charges for surgical operations, which would greatly add to it. Combine this with all the loss entailed by frauds practised, which latter would probably greatly exceed this amount, and one can see that the two amounts are enormously large, far beyond any necessity or justice."

If our Brooklyn confrères are disturbed now, what will they be when the dispensary system reaches New York's proportions? Brooklyn has about one thousand physicians and 665,000 inhabitants; New York has about three thousand physicians, over twice the population of Brooklyn (1,481,920), and about forty dispensaries, at a low estimate. Six of these alone treat about one hundred and twenty-five thousand patients annually.

News of the Week.

Surgical Mishaps.—An interesting pamphlet, just out, is "Surgical Mishaps," by Professor Nussbaum, of Munich. It has often been asserted that the younger members of the profession especially could profit more by the publication of the failures in medicine and surgery than by the publication of successes. Viewed from this point, Nussbaum's paper will be a very welcome and useful novelty. Some mishaps which Nussbaum relates have a comical besides the necessarily tragical feature. He tells us, for instance, of the case of a peasant who, many years ago, was taken to the clinics of a great medical centre in order to be treated for multiple ulcers of both legs. On being examined on the operating-table, the right leg was pronounced to be curable, while the left was declared to be incurable and to require amputation. The amputation had scarcely been performed when the surgeons found, to their great horror, that they had amputated the wrong leg! Their chagrin was still increased when the right leg, which by accident had been saved, healed in a short time spontaneously.—Berlin Correspondent, *Medical and Surgical Reporter.*

Death by Electricity: the New Method of Executing Criminals.—The law requiring electrical executions of death-sentences will go into effect on January 1st. The experiments on dogs made last summer by Harold P. Brown, an electrical engineer, were criticised because the weight of the animals killed was less than that of a man, and it was supposed that more current would be required to kill a human being on that account. On Wednesday afternoon Mr. Brown had an opportunity to make a demonstration before Mr. Elbridge T. Gerry, the author of the new law, and the committee appointed by the Medico-legal Society to report on the best means of putting the law into effect. It was sought to find out the amount and character of current that would be required to make death certain and instantaneous. The experiments were made in Mr. Edison's laboratory in Orange. The first victim was a calf weighing 124½ pounds. The hair was cut on the forehead and on the spine behind the forelegs, and sponge-covered plates, moistened with a solution of sulphate of zinc, were fastened in place. The resistance of the animal was 3,200 ohms. An alternating current of 700 volts was applied for thirty seconds. The animal. however, was killed instantly. It was at once dissected by Drs. Ingram and Bleyer, but the brain, heart, and lungs, were found to be in a normal condition, and the meat was pronounced fit for food. One metal plate carrying the current touched the hair of the forehead and slightly burned it, but otherwise there were no external indications of injury. A second calf weighed 145 pounds and had a resistance of 1,300 ohms. The deadly alternating current at 700-volts pressure was applied for five seconds, and produced instant death. To settle permanently the weight-question, a horse weighing 1,230 pounds was next killed by passing the alternating current at 700 volts from one foreleg to the other. The resistance of this animal was 11,000 ohms. Mr. Brown was assisted by Mr. A. E. Kennelly, and there were present Mr. Thomas A. Edison, Professor R. Ogden Doremus, Professor Charles A. Doremus, Dr. Frederick Peterson, Dr. Frank H. Ingram, Mr. Elbridge T. Gerry, Mr. Galvin, Dr. J. M. Bleyer, H. Bourgouon, and Mr. John Murray Mitchell. The experiments are said to have proved the alternating current to be the most deadly force known to science.

Dr. Carolin R. Conkey.—At the meeting of the New Haven Medical Society, October 18th, Dr. Carolin R. Conkey, of this city, was elected a member of the Committee on Public Hygiene.

Dr Joseph W. Howe has been appointed Consulting Surgeon to Charity Hospital, New York, after a service of twenty years as Visiting Surgeon.

Dr. A. M. Phelps has been appointed Visiting Surgeon to same institution, in place of Dr. F. N. Otis, resigned.

Professor Gerhardt has just been elected to the Rectorship of Berlin University. The confirmation of Virchow's election was withheld for political reasons.

Sir Morell Mackenzie, according to a recent cablegram, has resigned his membership in the Royal College of Physicians.

A Great Subsidy.—According to the *Western Druggist,* $10,000,000 is expended annually in advertising patent medicines. Over half of this goes to newspapers, and chiefly to country newspapers.

Disinfection of Yellow Fever.—Some alarm is expressed regarding the new man-of-war the Boston, on account of the epidemic of yellow fever which appeared on board recently. The fact is recalled that the Susquehanna and the Galena, before the Boston, were known as "yellow-fever ships." They were cleansed and fumigated and exposed to the rigors of Northern winters, but the disease recurred nevertheless. Since that time, however, disinfection has become a science, and there is little doubt that the Boston can be thoroughly cleansed.

Dr. Maximilian Joseph Reinfelder died at Yonkers, on November 30th, from heart disease. He was born at Munich, Bavaria, March 4, 1821. He was graduated from the University of Munich in 1844. He came to the United States in 1854, and matriculated at the University Medical College in this city. He was graduated in 1869, receiving a certificate of honor. He was consulting physician to St. John's Riverside Hospital, at Yonkers, a Fellow of the New York Academy of Medicine, and a member of the Westchester County Medical Society.

Gouverneur Hospital, it is reported, has been temporarily closed on account of the development of diphtheria in its wards. The disease is said to have been introduced by the ambulance surgeon, Dr. Chalmers, who was so unfortunate as to contract diphtheria while attending a dispensary patient.

Beef, Milk, and Phthisis.—There can be no doubt that bovine and human tuberculosis are essentially the same disease, and that bovine tuberculosis may be transmitted to man by means of infected milk and meat. The necessity of prophylactic measures with this point in view has been urged by The Record for many years, and we are glad to see that the public press and legislatures have at last begun to recognize the fact. It is not probable, however, that the cow is the source of phthisical contagion in a large proportion of cases. The (pulmonary) phthisical age is from fifteen to thirty, after which milk ceases to be an important article of diet. Further investigation, however, on this point is needed.

MARINE HOSPITAL SERVICE.—The Supervising Surgeon-General of the Marine Hospital Service reports that during the year just passed there have been treated 43,203 patients, which is the greatest number of patients furnished relief in any year since the organization of the service. The receipts from all sources were $496,441.69, and the expenditures were $528,844.66, which amount was paid from the unexpended balance to the credit of this appropriation in the treasury.

PTOMAÏNIC GASTRO-ENTERITIS.—The last article from the pen of the late Professor Bamberger was a study of a case of gastro-enteritis from poisoning by ptomaïnes. The source of the ptomaïnes was some old sausages which the patient had eaten.

MEMORIAL TO THE PRESIDENT AND COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.—A large number of prominent members of the British Medical Association have drawn up the following memorial: "The undersigned members of the British Medical Association and others beg to direct the attention of the President and Council to the publication in the 1450th number of the *Journal* of the Association of the fac-simile of a 'script' by the late Emperor Frederick of Germany, referring to his treatment by one of his medical attendants. The publication of this document the undersigned regard as a violation of professional confidence, and its appearance in the *British Medical Journal* as discreditable to the medical profession in this country. They accordingly request the President and Council to take such immediate action as may be required to clear the Association and profession from the discredit now attaching to them in respect to this matter." Subsequently it appears that "at a council meeting of the British Medical Association a resolution was passed deprecating the publication of the details of the late Emperor Frederick's sickness as a violation of professional confidence. The council accepted the regrets of the editor of the society's organ concerning the publication of them."

THE CONSULTATION BY TELEGRAPH, described first by the London *Times*, in which Sir Andrew Clarke is said to have held converse with physicians at Vancouver's Island, we are informed, never occurred.

DR. H. D. SCHMIDT, of New Orleans, the well-known pathologist, died on November 23d. He had been an invalid for years.

TYPHOID FEVER IN NEW YORK.—There has been some newspaper discussion regarding an alleged increased prevalance of typhoid fever in New York. The statistics of the City Board of Health show, however, that the number of cases is about the same as last year. During the past two months there have been from twenty to fifty new cases reported monthly.

LEPROSY IN INDIA.—The official report gives 135,000 as the existing number of lepers in India, but there can be little doubt, says an English journal, that they already exceed 250,000, and that their numbers are steadily increasing. No attempt at isolation is made.

THE POPULATION OF FRANCE.—The first volume of the French census of 1886 has just been issued by the Government. It shows that in thirty-seven years the increase in the number of native-born Frenchmen has been less than 1,500,000. The number of births per year appears to be actually diminishing, even with a slowly increasing population. The illegitimate births amount to eight per cent. of the whole, and are increasing year by year. The number of living children per family in France is 2.07, which is believed to be a lower average than can be found anywhere else in the world.

THE WALKING MATCH which took place in this city last week illustrates the fact that the human locomotive apparatus can be made to go almost continuously for six days, that it progresses best at a dog trot or a walk, and that small men can go the farthest. According to the published reports the contestants lost very little in weight during this week's work, not more than one or two pounds. One hundred and thirty to one hundred and forty pounds seemed to be the average weight.

THE GALEN CLUB of London, has ceased to exist for want of support. Yet it numbered 240 members. Its objects were chiefly social.

THE DEATH OF PROFESSOR VON BAMBERGER, OF VIENNA, took place on November 9th, from an affection of the chest. He was born at Prague in 1822, and graduated at that university. In 1854 he was appointed an ordinary professor at Würzburg, which at that time was looked upon as being the leading medical faculty in Germany. At Würzburg Bamberger remained as ordinary professor of Internal Medicine for eighteen years; among his colleagues there were Schönlein, Virchow, and Scanzoni. There he published his chief works, "Diseases of the Heart" (1857), and "Diseases of the Chyliferous System" (1864). The latter has been translated into Dutch and Italian. Among his other writings may be mentioned his work on "Bacon of Verulam" (1865). In 1872 Bamberger was called to Vienna to fill the Chair of Internal Medicine, which had become vacant by the death of Oppolzer; he continued to discharge the duties of this post till the beginning of the present semester. Bamberger was the recipient of many honorary distinctions; he was an Austrian and Bavarian "Hofrath," a Knight of the Leopold Order, and President of the Imperial-Royal Society of Physicians of Vienna. In 1885 he was elected Rector Magnificus of the University of Vienna. The funeral procession, which took place on November 11th, was one of the most splendid which the Imperial city has ever seen.

BAMBERGER'S SUCCESSOR, it is said, will be Professor Schrötter, a gentleman widely known as a laryngologist. He is said, however, to be also a general practitioner of great ability.

VERDI'S HOSPITAL.—A hospital has been entirely built by Verdi, the composer. It occupies a commanding site overlooking the Po at Villanova, with a distant view of the Apennines. There are two wings, one for women, the other for men, and a separate ward is set aside for contagious cases; there is also a hydrophathic establishment, and most elaborate arrangements have been made for the disinfection of linen and other sanitary purposes. An efficient staff of nurses and attendants is also provided, and Signora Verdi has made the housekeeping department her special care. Verdi himself has deposited sufficient funds for the future maintenance of the hospital. It was opened on November 6th, without ceremony, only Verdi and his family, the physician, and the Sindaco of Villanova being present. The Sindaco proposed that the new building should be called "Verdi Hospital," but to this the donor objected, and the name Hospital of Villanova was finally adopted.

The Poor Horse.—Our esteemed contemporary, the *Virginia Medical Monthly*, publishes the picture of a horse which is suffering contemporaneously from thirty-four different diseases. The trouble begins in front, or cephalad as they say in Ithaca with a carious jaw, and ends caudad with what is technically known as a rat's tail. The *Monthly's* polypathologic picture must appeal powerfully to the sympathies of its numerous readers.

A Chicago Christian Scientist has recently come to grief in Birmingham, England, having been sentenced to five years of penal servitude for indecent assault upon a little girl. The man announced himself as "Professor McLean, M.D., former president of the Mind-Cure Association, and editor of the science department of the *Medical Science Journal*, Chicago."

The Origin of the Yellow-Fever Epidemic.—Cuban smugglers are now being blamed for the introduction of yellow fever into Florida. The Sanitary Inspector of the United States Marine Hospital Service at Havana, Dr. D. M. Burgess, has made a report to Surgeon-General Hamilton regarding the matter, in which he demonstrates at least the extreme probability of these illicit purveyors of rum, cigars, etc., bringing disease-germs into the State. There are about fifty vessels, ostensibly fishing-boats, which are engaged in the business, and make little secret of it. They are not only dirty and fit vehicles for contagion, but their surroundings while in port are of the sort most likely to communicate any germs there may be in the sewage of the city to them. Dr. Burgess states, in conclusion, that open, well-regulated commerce in clean ships, observing all the methods of modern sanitation, and carrying only acclimated people, is perfectly safe in comparison to this smuggling trade.

Oxygen not so Important in Respiration.—M. Brown-Séquard, who is nothing if not original, recently read a note at the Société de Biologie in which he asserted that oxygen was not so necessary to respiration as had been supposed, and that carbonic-acid gas was not so poisonous as had been claimed. He had succeeded in keeping animals alive and comfortable in an atmosphere containing sixty per cent. of carbonic-acid gas, while he and M. D'Arsomal had been able to breathe an atmosphere containing twenty per cent. of CO_2 without any inconvenience. It is usually taught that air containing ten per cent. of CO_2 is poisonous. Brown-Séquard thinks that nitrogen is a very important element in respiration.

Virchow on Artificial Deformities.—What is the use, says Virchow, of introducing the principles and appliances of hygiene into the huts of the poor and ignorant, when the scions of wealth, pretended intelligence, and fashion, especially in the gentler sex, show their contempt of hygiene by their dress and general wearing apparel? In days gone by, the speaker said, I have battled against the diabolical invention called the corset; but this crusade has been given up by me as absolutely futile. The French shoe, with pointed toe and the heel under the middle of the foot, is another fashion which, on account of its detrimental influences on the body, cannot be opposed too energetically. Even the modern stocking, pointed and symmetrical, is injurious to health, as it does not conform to the anatomical formation of the foot. To offset this we notice that the professor of pathology at the University of Cambridge, Dr. C. S. Roy, and his demonstrator, Mr. G. Adams, have appeared as champions of tight lacing. Moderate pressure on the abdomen, they say, tends to assist the emptying of the abdominal veins, and experiment showed that the amount of blood expelled by the heart at each stroke was greater, and that consequently the blood-supply of the brain and spinal cord, the muscles and skin, was increased. This increased supply, they say, is useful when violent muscular exertions were being made; consequently tight lacing in women and tight waistbands in men are useful.

An Indianapolis Doctor who will Advertise.—"I'll blow my own horn and they can go to h—l," was the rejoinder of a prominent physician of Indianapolis, about one year ago, when remonstrated with for his unethical and ungentlemanly practices. True to this declaration, he is still blowing his own horn through the mails and the daily papers in the most shameless way; but one of these days the Marion County Medical Society will make old *terra firma* as hot for this auto-hornblower as the region to which he invited some of his compeers. —*Indiana Medical Journal.*

Typhoid Fever Stories.—Dr. Yount, of Lafayette, says that: "The season for snake and sea-serpent stories is now about past, but the woods are full of doctors who claim to have never lost a case of typhoid fever."

For Vomiting of Pregnancy, very good results have been obtained from ʒ ss to ʒ j. doses of fluid extract viburnum prunifolium. It has been extensively tried in Bellevue and other city hospitals. In a series of eight cases, in which it was recently given in ʒ j. doses, a uniformly successful result was obtained. It seems to have a direct action on the uterus itself, thus preventing the reflex irritation which results in vomiting. In some of the hospitals all other remedies have been discarded.—*Canada Lancet.*

The Still Pens in Cleveland.—"The condition of 'solitary confinement at hard labor,'" says the *Gazette*, "to which the profession of Cleveland has allowed itself to become accustomed, is recognized and often commented upon by the profession of the country." We are sorry to learn that Cleveland doctors do not write; but we trust that when they do, they will write well. There are worse things than not writing medical articles, *e. g.*, writing poor medical articles.

Verdict of Malpractice in Administration of Chloroform.—*The Lancet* states that a death from chloroform occurred in Sydney; and a lawsuit brought by the husband of the deceased resulted in a verdict of guilty, setting the damages at £200, on the ground that the anæsthetic was improperly administered.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN PRACTICE OF MEDICINE.

Stated Meeting, November 20, 1888.

R. C. M. Page, M.D., Chairman.

Dr. Debout d'Estrées, of Contrexville, France, read a paper (see p. 665) entitled

OXALURIA, ESPECIALLY IN ITS RELATIONS TO URIC ACID.

Dr. E. L. Keyes said he feared to enter upon the discussion of the broad subject of oxaluria, since it would involve the expression of views regarding the influence of the nervous system, digestive system, heredity, etc., requiring too much time. While he accorded entirely with Dr. Debout regarding the causes of oxaluria, he did not entirely accord with him in the statement that it was only seen in patients who had dense urine. Dr. Keyes had certainly seen oxaluria, and some of the severest examples, accompanying light and phosphatic urine in people of the United States who had more or less catarrh of the intestines and stomach, who were nervously prostrated or had various forms of neurasthenia. Whether the oxaluria was entirely dependent upon the neurasthenic state, with prostration and phosphatic urine, he could not say, for these conditions might exist without the presence of oxalate of lime, or when this was present in the urine the condition named might disappear without the disappearance of the oxalate of lime. According to his view the oxaluria was often an accompanying symptom of the conditions named, and not necessarily a cause of them. But that there was such a place upon the earth where oxalate of lime would disappear from the urine when a certain course was pursued was a pleasant fact to know. He alluded to the springs at Contrexville, in the Vosges. Dr. Van Buren had had some pleasant experience with the springs, and Dr. Keyes had sent patients there who had a catarrhal condition of the pelvis of the kidney, and more or less catarrh of the bladder, and they had been benefited. Of course, it would be absurd to say they were cured. He remembered one case particularly, that of a man who had a great amount of oxalate of lime crystals in his urine, and after staying at the springs a while, fine uric-acid crystals took their place. During the winter after his return the oxalate of lime again rep'aced the uric-acid crystals; consequently it could not be said that he was cured. Further, the symptoms of nervous depression from which he had suffered did not disappear with the disappearance of the oxalate of lime. What would have been the result in this respect had he stayed longer at the springs he could not say. But he was benefited in many ways. This patient passed a stone after his return home, and was subsequently well.

Dr. Keyes thought the proper treatment of a subject of oxaluria who was in robust health was exercise, air, and regulation of the diet. In debilitated subjects, build up the nervous system, control the catarrhal condition of the intestinal tract, if any existed, and restore the general health. The springs of this country had been of some benefit because of their diuretic and mildly cathartic effect, but they had not caused oxalate of lime to disappear from the urine as positively as did those at Contrexville. The latter-named springs he found, during his visit last summer, extremely pleasantly situated, largely attended by well-to-do Englishmen suffering from oxaluria or uric-acid diathesis, and among others he met Playfair, who was very enthusiastic over the springs.

Dr. George B. Fowler agreed with Dr. Goldenberg that the presence of oxalate of lime in the urine, independent of its presence in the food, had a pathological significance; that it was encountered in certain cases of indigestion, associated with symptoms of depression, general nervousness, or the condition which had been called the oxalic diathesis; that it could be present also as a result of imperfect oxidation from heart or lung difficulties. It was a product of imperfect oxidation of nitrogeneous matters, and when good digestion and assimilation were restored, including healthy breathing and circulation, the oxalate of lime disappeared. The question of the origin of oxalate of lime was very difficult to solve.

Dr. Fowler adhered firmly to the view that we had, on the one hand, the ordinary substances taken as food, divided into organic and inorganic, and, on the other hand, the complete oxidation, the acid, and smoke of that food represented by urea, carbonic acid, and water; and that imperfect oxidation and any interference with the preparation of the food in the alimentary tract would cause an excess, a pathological quantity of uric acid and oxalic acid. In order to determine whether the presence of the acid was pathological, it was necessary to eliminate its source in the food, for it was a prominent constituent of vegetables. The urine of all herbivorous animals contained oxalic acid in excess, while the normal urine of man contained it only in minute proportions, if at all. The treatment was dietetic. A simple diet, which could be thoroughly digested, was indicated, and it would depend upon the individual as to what that diet should be. While oxalate of lime was extremely insoluble, and consequently the free use of water could not prove of benefit because of solvent powers, yet it was of benefit in stimulating the glands and promoting assimilation, and it was to the plentiful water drunk at springs that he would attribute their remedial powers.

Dr. Debout d'Estrées closed the discussion. He had made some thousand examinations of urine of patients in France who had oxaluria, and had never found it with phosphatic gravel. He had generally observed in his examinations of oxalic-acid urine that it was more acid than urine in the healthy, or than when the patient had uric acid.

Regarding cure, he had not said that patients when they left Contrexville were cured, but that the urine contained no more oxalic acid until they might return to conditions in which it would again develop.

As to Dr. Fowler's remarks, he also quite agreed with the views quoted from Goldenberg as to nervousness and dyspepsia, but he was particularly anxious to hear from American physicians why their countrymen often had oxaluria while the French people had uric-acid urine. As to the large quantity of water drunk at the springs being alone the explanation of the benefit there derived, it could not be, for patients were not permitted to drink the quantities which they did some years ago at the alkaline springs, as Vichy.

THE TREATMENT OF FUNCTIONAL AND CATARRHAL DISEASES OF THE STOMACH AND BOWELS.

Dr. W. W. Van Valzah said his paper would be entirely clinical, and would treat almost exclusively of catarrhal conditions of the stomach and bowels, with a few remarks on functional diseases.

In all cases the treatment of catarrhal conditions of the stomach and bowels was largely one of diet, and that diet in nearly all was composed largely of animal foods, and in some instances it was necessary to limit the patient for a time exclusively to animal food. In other cases it was necessary to impose only slight restrictions upon the diet. Between these extremes there ranged a great variety. If animal food was called for, the best, as all knew, was beef. In severe cases beef pulp particularly was called for. The best part of the beef was the centre of the round steak, from the well-fatted corn-fed steer, from three to six years old. The steak should be from a half to three-quarters of an inch thick, not pressed too hard, broiled, and to it a little butter, salt, and pepper be added, or some flavor, as that of an extract of meat, might be imparted. In the early stage of a severe case of catarrhal disease the quantity of the steak should be very small. In a few instances no solid beef was borne. Later on, as the patient improved, the amount was increased, say to four or six ounces daily, then to ten, twelve, or even sixteen ounces. If it became very tiresome, change to lean chop, or grouse, or English pheasant. Even in the grave cases it might be well at first to give a small quantity of starchy food, but in the severer catarrhal conditions of the stomach the sooner the patient was brought to an animal diet the more quickly would he reach a state of comfort. Where there was catarrh of the bowel the same rules applied, but less rigidly.

When the appetite was at fault, it was invariably due either to bile on the stomach, indigested food in the stomach, or depression of the nervous system, to such a degree as to make the patient literally too tired to eat. The end should be to cleanse the stomach as rapidly as possible, limit very emphatically the amount of food, and insist on physical and mental rest; at the same time brace the nervous system by medicines, massage, and electricity. It was well in all cases, particularly of catarrh of the stomach, to keep the patient from one to three months on food which he could thoroughly digest from day to day, otherwise a permanent cure could not be expected.

In some cases a desirable food was milk warm from the cow. Ten minutes should be taken in drinking a glass. The next best thing to fresh milk was peptonized milk or half a glass of ordinary milk, to be increased if well digested. The patient might take both meat and milk, and no other food would give as good results.

If other foods, such as peas and string beans, fresh from the garden were given, much stress should be laid upon limited quantity. Little by little the diet might be extended until ordinary diet had been reached, but if the patient did not digest it well, he should return to the restricted diet. One could not be got so well that it would be impossible for him to become sick.

The principle at the foundation of the treatment was to stop the excessive fermentation in the stomach and intestines. The physician should be judge of whether the food was being digested, not the patient. To prepare the stomach for the food which a clean stomach would invariably digest there was no simpler means than hot water. It was a diluent, solvent, and stimulant, and particularly promoted downward peristalis. Among drugs which cleansed the stomach were soda and potash salts. Upward peristalis was in some cases a very annoying and difficult feature to control. Cold water seemed to promote upward peristalsis, while hot water had the reverse effect, promoting downward peristalsis. He could give no explanation.

The specific gravity of the urine should be kept at 1.012 to 1.015. At the beginning of the treatment it was well to tell the patient to take a glass of hot water, from 110° to 120° F., an hour before each meal, and on retiring, to consume twenty minutes in drinking it. If there was marked catarrh of the stomach it should be taken two hours before the meal. If disagreeable to the taste, add a little lemon juice, etc.

The drinks at meals should be limited to one of three things, viz.: black tea or coffee (not more than one clear cup after a meal and one early in the morning), or milk. When there was marked malaise he might give a cup of very strong black coffee to which there should be added from one-sixteenth to one-twentieth of a grain of sulphate of strychnine.

The indications for medicines were, to supplement the gastric juice, to promote appetite, to invigorate the nervous system, to check or stimulate the secretions. Other advanced or marked symptoms might have to be met. Give such medicines as would not disturb the stomach, the less needed the better. In chronic inflammation of the duodenum, medicines directed immediately to the mucous membrane certainly gave good results. Among these none were so good as hydrastis, alone or in combination with bismuth. Small doses of iodide of potash or Merck's salicin might be useful. A free movement of the bowels should be obtained each day, and if necessary a laxative administered, as Carlsbad salts, licorice powder, etc., or a non-irritating enema of olive-oil and glycerine. For acidity, there was nothing better than salicylate of soda, or rhubarb and soda. Salol had not been useful in his hands.

The management of the mental condition of the patient was of extreme importance. He should be seen often, and the doctor's visit was a failure if he did not leave the patient in a hopeful state. Insist upon his resting half an hour before each meal, and sleeping from eleven to thirteen hours daily.

Fermentation in the bowels, even when excessive, was a stimulant, especially when alcoholic, and when checked by treatment it might have a weakening influence on the patient. A little brandy one or two hours after meals would counteract the depression.

Daily examination of the stools should be made, particularly in functional diseases of the alimentary tract. It was very important to study each case carefully and treat it according to its merits.

Dr. A. Caillé opened the discussion. To intelligently treat dyspepsia it was necessary to have in mind a good classification of the different forms, and as such a classification was difficult to found on pathology, he had made it clinical. First, there were acute and chronic dyspepsia. The acute form came from an overloaded stomach, and would pass off in a day or so. Acute gastric catarrh might run a course of one or two weeks, with or without fever. Under chronic dyspepsia he found the classification below of practical value: simple nausea, gastric vertigo, dyspepsia from insufficient mastication (bad teeth), simple loss of appetite, which might be due to old age; acid pyrosis, dyspepsia of pregnancy, of anemia, from disease of the heart, ulcer of the stomach, and nervous dyspepsia.

Regarding diet, he rarely had to order exclusively liquid or peptonized food, and he usually got along better by employing a liberal diet of articles which he had found by experiment were well borne by the patient. Experience had shown that patients of this class could not take cheese, lobster salads, cabbage, fresh bread, pastry, and beans. Some patients could take fruit, others could not. As a rule stewed fruit was less likely to do harm than raw. He agreed with the author that milk should be taken slowly, and in soups; the addition of a little cracker or bread made it coagulate in smaller particles. Contrary to what might seem good advice, he gave his patients liberty to use salt pickles and green salads. They seemed to stimulate the mucous membrane to activity, and usually the patients liked them.

As to medicines, he usually began with a dose of calomel and jalap, or podophyllin. Afterward a mineral acid, as hydrochloric, in combination with wine of pepsin, etc. In pyrosis, or heartburn, an alkali was supposed to be indicated, but he knew by experience that dilute muriatic acid was just as good in many cases. The first dose sometimes caused pain in the tender stomach, and if that occurred, the patients should immediately take some morphine, or morphine and chloroform, and omit the hydrochloric acid a day or two. If the medicinal and dietetic treatment was not sufficient, then wash out the stomach, using the soft tube. If the water came back clear, the irrigation would not prove useful. In anæmic dyspepsia, give iron, strychnine, or arsenic. The strong tobacco used in this country sometimes caused dyspepsia, in which case it should be dropped.

Dr. Henry Schweig thought the subject of diet had been excellently elaborated by the author. In gastritis and gastric catarrh there was, in his opinion, no such thing as an established diet. It should be adapted to each case. The paper seemed to treat of these affections too much as if they were strictly local. He thought they were frequently conjoined with lesions elsewhere, and would not disappear until the latter had received attention. For instance, he had seen some catarrhal conditions of the stomach disappear only after treatment of a catarrhal affection of the respiratory tract. Regarding remedies, he had found nitro-muriatic acid of use, and also oil of wintergreen.

Dr. John C. Peters allowed a great variety of diet in the course of the day, but only a very few articles at one meal. For instance, before rising the patient took a cup of hot coffee or cocoa; for breakfast, simply meat and a bit of bread and toast. Every two or three hours afterward during the day he might take one or two articles, as potatoes with butter, or rice with milk, etc. In simple catarrh of the stomach he relied largely on liquor potassa; pulsatilla was useful; sometimes also astringents, mineral acids, and bismuth.

Dr. F. W. Jackson thought the reader of the paper should have made a clearer distinction between catarrhal conditions of the stomach and those of the intestines. The treatment laid down seemed better suited to severe cases, but it would be difficult to carry it out in but a limited number. He agreed in the view that dietetic treatment was most important, but perhaps the author had not allowed sufficient freedom in this regard. In intestinal disorders certain anti-fermentatives were of value, as salol, salicylic acid, naphthol, etc., which, however, were only adjuncts to hygienic management.

The Chairman, **Dr. R. C. M. Page**, mentioned a case which impressed the necessity for inquiring into the cause of the gastric or intestinal trouble. A boy, ten years of age, had been failing in health two or three years, and was thought to be going into consumption. Dr. Page finally saw the lad, and careful examination revealed no disease of the heart, lungs, or other organs, but in the fæces he found sand. The patient had been accustomed to eat sand which was about the yard, and when he was removed from this, and without any treatment, he became fat and healthy. In all rebellious cases, therefore, examine the fæces, and thus learn, what one may not be able to do otherwise, what the patient eats.

Regarding Carlsbad salts, such as they obtained at the drug stores, it was only sulphate of soda, for which seventy-five cents or a dollar had to be paid, when, if purchased under its true name, it would cost but five cents.

Dr. Van Valzah closed the discussion, and said his paper was a plea for more exact observation and methods in the treatment of gastric and intestinal catarrh.

Blood Calculi in the Ovaries.—Dr. H. W. G. Mackenzie, at a late meeting of the Pathological Society of London (*The Lancet*, October 20, 1888), exhibited a specimen of concretions in the ovaries from a woman, aged forty-one, who had suffered from menorrhagia for two years, and had a large fibro-myoma of the uterus. She had disease of the mitral valve and fatty degeneration of the liver. The uterus was uniformly distended by the tumor, which was a globular mass about four inches in diameter growing inwards from the uterine wall on the left. The uterine walls were themselves hypertrophied. The ovaries, which were enlarged, contained a large number of black, hard, flat concretions of sizes varying from a coriander seed to a bean, of irregular shape, smooth, firm, and hard, although they could be cut with a knife. The concretions were in cavities, two or three together. Microscopic examination of a thin section showed absence of structure. The concretions were exceedingly insoluble in acid and alkaline solutions, and were only slowly dissolved by digestion in the gastric juice. They probably consisted of coagulated proteids, and were akin to the colloid concretions found in the prostate and in old hemorrhages. The specimen was a very uncommon one, perhaps unique. The enlargement of the organs was probably due to chronic congestion, the consequence of the large uterine growth. The concretions, it was suggested, were derived from hemorrhages into Graafian follicles, the effused blood having undergone a rare colloid change.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, November 2, 1888.

Francis P. Kinnicutt, M.D., President, in the Chair.

Dr. Andrew H. Smith read the paper of the evening (see p. 666), entitled,

MANAGEMENT OF PROGRESSING CEREBRAL HEMORRHAGE.

Dr. C. L. Dana said that he had already carried out a part of the treatment suggested by Dr. Smith, in several cases, though not on exactly the same grounds. He had given the nitrites because he thought the indications were to reduce arterial tension. Certainly an atheromatous artery is less liable to break when the tension is low. About a year ago he had seen a case in which cerebral hemorrhage had taken place. He saw the case several days after the hemorrhage had occurred, but the patient had not improved. He gave strophanthus hispidus and nitrite of amyl, and under this treatment the patient improved considerably. He had also had four or five other cases of a similar nature in which the same treatment had been employed, as he believed, with success in all. It is not, however, in all cases that this mode of treatment is indicated, for in plethoric patients the vaso-dilators are apt to do harm rather than good.

Dr. J. W. Roosevelt had tried the same methods of treatment, but without lowering the head. He was led to use the vaso-dilators by the same train of reasoning that Dr. Smith had employed. The idea was to lower the pressure in the cerebral arteries. He was at one with the reader of the paper in condemning the employment of ergot in these cases, and he thought that it was almost a disgrace to the profession that this drug should be so often used indiscriminately in all forms of hemorrhage.

Dr. G. L. Peabody said that it had always been his fate to reach these cases at a time when all activity had ceased. But could they be seen at the time that the bleeding was going on, the indication would certainly be to lower the arterial tension. Nitrite of amyl, contrary to the belief of some, does not increase the blood-supply to the brain. The use of other drugs of the nitrite order is not the same as that of amyl, because the other nitrites cannot exert their influence rapidly enough. He agreed with Dr. Roosevelt in his strictures upon the unreasoning employment of ergot in hemorrhage.

Dr. F. P. Kinnicutt remarked that his personal method of treatment of these cases had been much like that of Dr. Smith. For several years it had been his rule to give the nitrites in cases of cerebral hemorrhage. He gave nitroglycerine in frequently repeated doses, and had seen no harm result; but, on the contrary, was satisfied in his own mind that benefit had followed its employment. By means of moderately large and frequent doses of nitroglycerine we certainly can reduce arterial tension, at least temporarily. He agreed with the previous speakers in condemning the exhibition of ergot in these cases.

Dr. A. H. Smith said that nitrite of amyl was specially indicated in these cases because of its rapid action. It reduces the *vis a tergo* within the arteries, and at the same time causes additional pressure within the cranial cavity, thereby making compression at the seat of hemorrhage and so arresting it.

THE USE OF ERGOT IN ARRESTING HEMORRHAGE

is valuable only when the bleeding is taking place from capillary surfaces. In cases of hemorrhage from the nasal septum, we can often see the blood oozing from the mucous membrane when no lesion is discoverable. This is a true capillary hemorrhage, and in any case of such a kind ergot is indicated.

SOME DIFFICULTIES IN THE DIAGNOSIS OF TYPHOID FEVER.

The adjourned discussion on Dr. Ball's paper (see pp. 225 and 410) was now resumed.

Dr. A. B. Ball said that he had just had a practical illustration of the value of an examination of the blood in the diagnosis of doubtful cases. A physician living in New York had recently returned to the city from the country. At the hotel where he had been passing some time there had been a case of typhoid fever. A few days after his return he began to have chilly sensations in the afternoon. When he came to consult the speaker he had had chills in the afternoon on three successive days, and they were followed by fever, but no sweating. At the time of the visit, which was in the forenoon, he was entirely free from fever, but in the evening of the same day he had a temperature of 101° F. The following morning the temperature was again perfectly normal. At the speaker's request, Dr. W. B. James took three or four specimens of blood from the patient's finger for examination, but was unable to detect the presence of any malarial germs. The fever returned again in the evening, and another examination of the blood at this time showed the absence of malarial germs. The patient had been suffering severely from dyspepsia for several months, and Dr. Ball was loath to give him any quinine, but would have done so on account of the peculiar intermittance of the fever, had not this examination shown the absence of the plasmodium malariæ.

Dr. A. H. Smith said that he was particularly pleased to see that Dr. Ball recognized cases as typhoid fever in which there were no abdominal symptoms nor any eruption. He had seen several cases in which there were no symptoms of this sort. He thought it not improbable that the micro-organisms of typhoid fever were of several varieties, belonging doubtless to the same species, but differing among themselves. As regards

ERLICH'S TEST,

he had had a good many examinations made by the house-physician at the Presbyterian Hospital. The cases embraced a variety of diseases, and in some the reaction was present, while in others of the same disease it was absent. Of twenty cases of typhoid fever, however, the reaction was present in every instance, but in ten cases of convalescence from typhoid, after the fever had subsided, there was no reaction. In five cases of traumatic fever, with high temperature, the application of the test gave negative results. In reply to a question by Dr. Ball, he said he did not know the details of the application of the test in these cases, whether the reaction was found in the sediment of the urine or not.

Dr. Ball said that it was very important to take that precaution.

Dr. C. L. Dana said that he had found that there was a mistaken idea very prevalent as to what the reaction was, and it was not safe to rely upon statements concerning the results of Erlich's test unless the details of the process were thoroughly understood by those who applied the test. He had not found the reaction in many cases other than typhoid fever.

Dr. G. L. Peabody had been much interested in the application of this test. During the past few months about five hundred patients in the New York Hospital had been examined in reference to this point. In three cases of malarial intermittent fever the reaction was present. That the diagnosis in these cases was correct was shown by the fact that the plasmodium malariæ was found in the blood. The reaction was also found in other febrile affections, and also in one case of non-febrile diarrhœa. It was absent in five well-marked cases of typhoid fever, in which the plasmodium malariæ was not found in the blood, and in which quinine had been given without effect. The speaker had been unable to obtain the reaction in the later stages of typhoid fever, and also at earlier periods in almost all the cases in which antiseptics had been given. In these five cases, however, in which the test had failed, no antiseptics had been used, as far as known, and the disease was still in its active period.

Dr. W. H. Draper said that any one who has seen a great deal of typhoid fever must have a doubt in his mind whether he is not dealing with

SEVERAL FORMS OF CONTINUED FEVER

rather than with one. He also doubted whether there was any such thing as an aborted typhoid fever—that is, whether a case of true typhoid fever ever ran its course within one or two weeks. He agreed with Dr. Ball that true remittent fever was very seldom seen in this region of the country. Many cases were called remittent fever at first, but were found later to be true typhoid fever. There is so much confusion in the minds of different observers concerning this disease, that we must believe that there are forms of continued fever that are not typhoid, and which differ from the latter chiefly in their duration.

Dr. C. Cleveland looked upon the temperature as the most important guide in the diagnosis of typhoid fever, and he had frequently seen cases in which this was the only guide, the abdominal symptoms and the roseola being absent; indeed, in most of his cases there had been no eruption. He did not see why there should not be cases of aborted typhoid fever. In the case of scarlatina it is not unusual to see patients with very slight symptoms, which quickly pass away, yet they are undoubtedly suffering from scarlet fever. It is merely a difference in degree in the amount of poison taken into the system.

Dr. F. P. Kinnicutt said that he would only refer to one or two points in Dr. Ball's paper. He would emphasize the occasional most prominent localization of the typhic infection, even at the onset of the disease, in other portions of the body than the intestine. He cited a case which he believed to be an illustration of such a localization. An outbreak of typhoid fever occurred in a New York household, in which three of its members developed typical typhoid fever within a few days of each other. The disease in these cases pursued its usual course. Two other inmates (servants) of the same house were taken ill within a week from the occurrence of the first case, and were removed immediately to St. Luke's Hospital. In one the symptoms and physical signs at the onset had been those of a pneumonic process in the upper lobes of both lungs, with an accompanying acute nephritis (the urine containing blood, albumin in large amount, and casts of various kinds). Defervescence of the pneumonia occurred on the seventh or eighth day, the nephritis diminished, but the fever continued until the end of the third week. In the second case the symptoms and physical signs at the onset were those of a pneumonia of the lower lobe of one lung, running its course in seven or eight days, the fever only disappearing, however, on the fourteenth day. Dr. Kinnicutt had questioned, in the latter case, whether the pathological process had been a simple pneumonia or whether it should be regarded as an illustration of the localization referred to by Dr. Ball. Its development in an infected household, and the continuance of the fever after the subsidence of the pulmonary symptoms and signs, were certainly points of interest.

He would add a few words in regard to Erlich's test. The reaction to this test, it is well known, may obtain in various diseases, but without much regularity in such diseases. The important point, it seemed to him, was to determine whether it occurred in so large a proportion of cases of typhoid fever as to render it an important aid in diagnosis. This he believed to be the case. There were sources of error which had been mentioned by Dr. Ball, in employing the test, which might render it valueless in a given case. The rule at present adopted in St. Luke's Hospital was to use fresh preparations for each testing. In fifty consecutive cases of typhoid fever, treated in St. Luke's Hospital during the past year, the characteristic reaction had been obtained in all but four. These four had occurred during the hottest weather of the summer, and there had been a doubt at the time whether some chemical change in the reagents had not occurred. The failure of the test had been of much service to him in the probable exclusion of typhoid fever in several cases, an exclusion which the subsequent course of the disease justified. It was exceeding desirable that the failure of the test, carefully used, in any well-observed cases of typhoid fever, should be reported.

Dr. Kinnicutt believed that Laveran's discovery of the plasmodium malariæ promised increased facilities for differentiating malarial from typhic infection.

Dr. Ball said that Erlich himself had admitted that the reaction was occasionally absent in mild cases of typhic infection, and the speaker had also seen cases in which it was not present. Its absence certainly argued against the disease being typhoid, yet its presence did not point absolutely to the existence of this affection.

Dr. Dana had found the reaction present in all but one of his cases of typhoid fever, and that case was a very atypical one; the eruption was absent and the fever ran a very irregular course.

Dr. Draper said that his remarks had possibly been misunderstood. He admitted, of course, that there were cases of typhoid fever varying greatly in their severity. But he would not be surprised if we should find that other diseases existed in which the symptoms were similar to those of this affection, which were nevertheless not cases of true typhoid fever.

Dr. Peabody did not wish to be understood as calling in doubt the value of Erlich's reaction, for he agreed with Dr. Ball that it was a very valuable negative test.

Dr. A. A. Smith reported a case which simulated very closely typhoid fever, and had been diagnosticated as such, but the fever continued for so long a time that the correctness of the diagnosis began to be doubted. A more careful examination was then made, and it was discovered that pyelitis was present. The urine had been previously examined, but the presence of pus in the urine was not constant, and the pyelitis had thus escaped detection.

Dr. Beverley Robinson related a case which had been supposed to be one of typhoid fever, but at the autopsy no typhic lesions had been found. Small infarcts were discovered in the lungs and spleen and a phimosis being present, the prepuce was slit up and a suppurative disease of the glans penis was found to exist. In this case Erlich's reaction was not present. In another case, now under treatment, in which the urine responded to the test, and which was believed to be typhoid fever, a similar condition was present, the prepuce being gangrenous. It was probable that infarcts in the internal organs were present, yet it was believed that typhoid fever existed.

The Society then adjourned.

Where has 'Opkins gone?—*The Hospital*, of England, states that nurses in hospitals are rather apt to lay too much stress on the advantages received by the patients and their duty of thankfulness, but still it is the poor soldier who suffers most from always having his causes to be grateful flung in his teeth. Witness the following true story: Chaplain.—So poor Hopkins is dead. I should have liked to speak to him once again, and soothe his last moments; why didn't you call me? Hospital Orderly.—I didn't think you ought to be disturbed for 'Opkins, sir, so I just soothed him as best I could myself. Chaplain.—Why, what did you say to him? Orderly.—"'Opkins," sez I, "you're mortal bad." "I am," sez 'e. "'Opkins," sez I, "I don't think you'll get better." "No," sez 'e. "'Opkins," sez I, "you're going fast." "Yes," sez 'e. "'Opkins," sez I, "I don't think you can 'ope to go to 'eaven." "I don't think I can," sez 'e. "Well, then, 'Opkins," sez I, "you'll go to 'ell." "I suppose so," sez 'e. "'Opkins," sez I, "you ought to be wery grateful as there's a place perwided for you, and that you've got somewhere to go." And I think 'e 'eard me, sir, and then 'e died.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK

Adjourned Annual and Stated Meetings, November 26, 1888.

Dr. L. Bolton Bangs, Vice-President, presided at the adjourned annual meeting, and after reports of certain standing committees had been received he declared the meeting adjourned.

Dr. Alexander S. Hunter, President-elect, called the stated meeting to order. Before introducing the speaker of the evening, he made some remarks on the objects of the Society, dwelling upon that for the promotion of medical science and art. The best papers from the best men in the profession should be read at this Society, and the best discussions should be called forth. The subjects should be practical, and of a kind which interested all members of the profession. He had the promise of interesting papers by distinguished men, assuring them of a good audience, and he appealed to the members to be present at each meeting.

Dr. Hunter then appointed the following standing committees: On Ethics, Dr. F. A. Castle, Chairman, Drs. William H. Draper, H. E. Crampton, A. N. Jacobus, and N. J. Hepburn; on Hygiene, Dr. Richard Van Santvoord, Chairman, Drs. William H. Flint, Cyrus Edson, J. E. Andrews, and Sanger Brown; on Prize Essay, Drs. E. H. Grandin, M. Allen Starr, and William G. Thompson; Auditing Committee, Dr. C. E. Billington, Chairman, and Dr. William Stevens.

Dr. William H. Thomson then read a paper, entitled

SIGNIFICANCE OF COUGH AND USE OF EXPECTORANTS.

In this climate, he said, there was scarcely anything for which the physician was so often asked to prescribe as cough. To many persons it was such an ominous thing to hear that its prompt removal was earnestly sought for; if it was not removed it was regarded as the note of death. There was much to justify this dread. He doubted also whether any other kind of prescriptions were so little varied, after some years' experience, as each one's cough mixtures. They became as much a fixed habit as other habits, and were likely to last for life.

Cough was a reflex act usually, whose efferent mechanism was brought into play by a great variety of afferent impressions. Its one important object was expectoration, but much oftener than not the reflex act occurred without accomplishing its object, and it was therefore useless. One of the commonest indications to be met by the physician was to suppress a useless cough and allow only that which would accomplish its natural purpose.

To support this statement he would enumerate a number of useless or non-expectorant coughs. His list included not fewer than fourteen kinds of the most common, and doubtless those present could add others. All non-expectorant coughs had one marked feature in common, and that was the peculiar sound.

The sound of a non-expectorant cough, whatever its kind or origin, was single, while that of the expectorant cough was never single. That was to say, the non-expectorant cough, no matter how constantly or rapidly repeated, consisted of a series of separate acts, and might be likened to the separate blows of a hammer, which might be few or many, loud or just audible, occurring only now and then or in rapid succession, for a brief period or in paroxysms. The expectorant cough, on the other hand, was never single. It might consist of only one act of real coughing, but if so, it was immediately followed by a sound, an evidence of clearing the pharynx, which was the last step in expectoration as far as the respiratory tract was concerned. Generally, however, it consisted of a number of coughs, in which the sounds, instead of resembling the strokes of a hammer, were more like the sound of a chain passing over a pulley.

The secretions excited cough only when they reached the sensitive points in the respiratory passages, the existence of which had been pointed out by experimenters. Below the second division of the bronchi the secretions did not excite a desire to cough, but from this point up to the trachea the sensitiveness of the tract to foreign bodies increased, while in the trachea there was little sensitiveness. It reappeared, however, in the larynx. The continuous character of the expectorant cough was well illustrated in chronic bronchitis with very viscid expectoration, the catarrh sec of Laennec.

Passing to the varieties of non-expectorant cough, the first mentioned was that due to simple inflammatory irritation, without secretion, of some portion or of the whole respiratory tract from the epiglottis down to the third division of the bronchi. An instance of this was seen in the purely hyperæmic stage of bronchitis. The indication, was to turn the dry into the expectorant cough as soon as possible, by starting the secretions. He used tartar emetic, small doses in water, repeated until expectoration took place. A much more common example of this cough occurred in ordinary bronchitis, both acute and chronic, where, owing to the co-existence of secretions and more or less expectoration, it might be confounded with expectorant cough. The patient had a number of distressing, painful hacks, without bringing up anything; the cough, however, now and then terminating in the continuous kind. It was especially frequent in phthisis. He gave chloral and morphine in these instances for the non-expectorant cough exclusively; so far as the expectoration itself was concerned, they acted rather as drawbacks.

A second variety of useless cough was seen in inflammatory irritation of the pharynx. This was common enough in ordinary colds, but it was also one of the most obstinate troubles in advanced phthisis. Ringer's suggestion, to apply with a brush morphine with starch to the throat, would often enable the patient to get a night's rest. The specific effect of aconite on this part of the mucous membrane was frequently beneficial.

A third variety of useless cough was due to irritation of the pleura, and the importance of recognizing the pleuritic origin of coughs could scarcely be over-estimated. His rule was to strap the whole affected side six months or more after an attack of pleurisy. There was a dry, hacking cough of early phthisis which might be excited by laying the cold hand on the shoulders. The pleuritic cough could not be otherwise than harmful and provocative of increased inflammation in the lungs, and consequently he strapped the side. The objections thereto were only theoretical.

A fourth variety of useless cough was spasmodic, seen in pertussis. This could be wholly suppressed within a week by bringing the patient under the physiological effects of belladonna. If the child afterward took a cold there would be a new reason for cough.

A fifth variety was the malarial cough, sometimes mistaken for whooping-cough, and curable by quinine. A sixth variety was the nocturnal cough of children from irritation in the intestinal canal. A seventh variety was the so-called uterine cough, although it might start from the uterine appendages rather than the uterus. It was also present in hysterical women, and was often very loud. Purgatives, as of rhubarb, also asafœtida, valerian, and bromides, were of benefit, but when disease of the genital organs existed it should be treated.

Then there was the useless aneurismal cough, the diagnosis of which could be facilitated by listening over the trachea for a persistent croupy sound, no matter how quiet the respiration. It was best relieved by morphine, but it could often be warded off by a couple of leeches over the sternum. Similar to it was the useless cough induced by pressure of an enlarged gland against the pneumogastric. With it there was hoarseness and vomiting, which the doctor could assure the parents would disappear after a while with the softening of the gland. It might be relieved by dry-cupping between the shoulders. Another instance of reflex useless cough was due to wax or foreign bodies in the ear. There were coughs also from irritation of the phrenic nerve, in perihepatitis, abscess of the liver, and some cases of splenitis. Cerebral cough was of grave import, and likely to be excited by affections at the under surface of the cerebellum, or tumors or abscess pressing down upon the medulla oblongata.

The indications for the treatment of expectorant coughs were simple, and two in number, namely, first, to make the phlegm more liquid and easy to expel, and, second, to make the cough powerful enough to be effective. A third might be added, to check or diminish superabundant secretion. There was a close connection between the œsophagus and the respiratory tubes, and in the dyspnœa of pneumonia he had often kept the children swallowing half a teaspoonful of milk and lime-water for long periods, with the best results in promoting expectoration.

All oils increased the flow from the mucous membranes, but certain oils affected more certain secretions. Experience had taught him that the best oil for increasing the secretions in the respiratory tract was linseed. He had not found this mentioned in any of the books. When prepared by emulsion it was not difficult to administer. It was more effectual than any other expectorant in rendering the bronchial secretion less albuminous, less viscid, and facilitating expectoration. It markedly diminished bronchial irritation. It was of use in the asthmas affected by change of weather, etc. It was useless in capillary bronchitis, and of little value in broncho-pneumonia. Where the bronchitis was primary and local in origin linseed-oil was indicated.

The emulsion when made in quantity was composed of 15 ounces of linseed-oil; 2 drachms each of oil of wintergreen and oil of cinnamon; 10 ounces of powdered acacia; water, 24 ounces; glycerine, 5 ounces; simple syrup, 10 ounces, dilute hydrocyanic acid, 2½ drachms. To be churned. Half an ounce constituted a dose. To six ounces he might add forty minims of Magendie's solution, and a drachm and a half of chloral.

Dr. A. Jacobi took exception to some statements in the paper. For example, he doubted whether we could make a reliable diagnosis of enlarged bronchial glands as the cause of non-expectorant cough, and he enumerated the difficulties. He also called attention to some neurotic useless coughs, not only in women, to which class Dr. Thomson had alluded, but also in men and children. Pharyngeal cough was frequent, and when due to an elongated uvula was likely to be present when the patient lay down. Often this cough was present at night, or when the patient arose in the morning, and was due to dry secretions acting as a foreign body. The enlarged tonsil could be excised or burned. A further remedy for the symptom consisted in frequent sips of warm alkaline water.

Dr. Beverley Robinson insisted upon it that the physician should not mix all sorts of things together in his prescriptions. If he had a good thing it should rest on its merits. If linseed oil was good, give it as linseed-oil, and not mixed with a variety of things which would make it impossible to say to which drug the beneficial effect was due. Scarcely any mention had been made of conditions of the nose and naso-pharynx producing cough. He would not want his chest strapped six months for pleurisy; better remove the effusion and prevent adhesions. From certain experiments he had been at one time disposed to think the area of cough was in the apex of the lungs.

Dr. Clarence Rice dwelt somewhat upon conditions of the naso-pharynx as a common cause of cough, and mentioned particularly enlarged veins or papillæ at the base of the tongue.

Dr. Simon Baruch thought the paper gave too much attention to semiology, especially as a basis for diagnosis and treatment. He believed in the experiments which went to show that of so-called expectorants there were only two in fact, namely, apomorphine and pilocarpin. There was only one way of removing an irritating or so-called non-expectorant cough, viz., by the use of a neurotic.

Dr. O. K. Tansley mentioned some affections of the ear, causing irritation of the external canal, as giving rise to cough.

Dr. Darlington had known linseed oil to be used considerably in the country in cough, with good effects. Until recently he had noticed it only in the hands of housewives. They did not mix it with any other remedies. He called attention to a cough in men who worked in the New Aqueduct, caused by the gases given off after explosions of dynamite. It was an irritant cough, and had been mistaken as a symptom of other diseases by some hospital physicians. It was relieved only by large doses of morphine or chloral.

Dr. Thomson in closing the discussion pointed out the diagnostic signs of enlarged bronchial glands; said the scope of his paper was necessarily limited, and with regard to mixing together a variety of drugs for a given indication, that those added to the linseed-oil, with the exception of the hydrocyanic acid, were to effect an emulsion.

Dr. H. T. Hanks then read,

A MEMORIAL OF DR. J. B. MCINTYRE.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE BOWMAN LECTURE—THE VALUE OF EYE-SYMPTOMS IN THE LOCALIZATION OF CEREBRAL DISEASE—A PECULIAR CASE OF ASCITES—ARTHRECTOMY *VS.* EXCISION OF JOINTS—THE RADICAL CURE FOR HERNIA AND ITS PERMANENCE—THE ARMY MEDICAL RESERVE—THE EPIDEMIC OF DIPHTHERIA IN LONDON.

London, November 17, 1888.

In the "Bowman Lecture" recently delivered before the Ophthalmological Society, Mr. Swanzy, of Dublin, chose for his subject "The Value of Eye Symptoms in the Localization of Cerebral Disease," and gave a valuable summary of the present state of our knowledge on the matter. He divided the subject into two parts, according as there were oculo-motor disturbances or disorders of the visual apparatus. Of the former the most common was conjugate lateral deviation of the eyes, which might indicate a lesion either of the cortex, the internal capsule, or of the pons. In the former cases the eyes were turned toward the lesion and away from the paralyzed limbs, while in a lesion of the pons the opposite condition was present. The exact location of the lesion in the pons might be ascertained by additional ocular symptoms. Thus ptosis or paralysis of the sixth nerve might be also present; in the latter case the affected eye would remain permanently deviated. A lesion low down in the pons would cause paralysis of the sixth nerve, without any conjugate deviation. Paralysis of the other associated movements of the eye was rare, and generally corresponded with a lesion of the corpora quadrigemina. Ptosis alone was not uncommon, and, when present along with paralysis of the opposite side of the body, would point to disease of the crus. If the paralysis did not come on at the same time it would be probable that two separate lesions were present. Complete paralysis of the third nerve pointed to a basal lesion, as also did isolated paralysis of the fourth or sixth nerves. If the paralysis of the sixth nerve were accompanied by hemiplegia on the opposite side of the body, the pons was probably affected; if the hemiplegia were on the same side, a cortical lesion was indicated. Nystagmus was of no value in localizing a cerebral lesion, and Mr. Swanzy did not think the state of the pupils afforded much information. Persistent dilatation of one pupil, however, indicated paralysis of the third nerve.

In the examination of visual defects the co-operation of the patient was necessary, and he must possess some intelligence. Hemianopsia was the most common visual defect, and was of great localizing value. The lecturer treated this portion of his subject at some length. He pointed out that hemianopsia might be due to a lesion of the posterior third of the internal capsule, or of the optic tract. In the former case it would be accompanied by hemianæsthesia of the opposite side of the body, and, if the brain-lesion were on the left side, by aphasia also. If a lesion of the optic tract were suspected to be present, an examination of the state of the pupil would afford assistance in diagnosis. If the light were concentrated on the blind side of the field and the pupil did not react, the lesion must be in the optic tract; if the pupil did react, the lesion was evidently not in the optic tract.

At the Medical Society, on Monday evening, Dr. Gulliver read the notes of a case of ascites simulating ovarian tumor. The patient was sixty-three years of age, and the symptoms from which she had suffered previous to admission were pain in the back, swelling of the legs and abdomen, inability to retain her water, and vomiting. On admission the abdomen was found enlarged, and there was dulness on percussion all over, this being more marked on the right side. There was a zone of resonance in the left flank. It was thought that there was an ovarian tumor and the patient was tapped, nearly a gallon of fluid being drawn off. The dulness immediately became more unilateral, but later on became as extensive as before. The vomiting persisted and albumen was found in the urine. The albuminuria and the age of the patient precluded the idea of operative interference. It was thought that the diagnosis lay between ovarian tumor and ascites shut off by vertical adhesions. The patient died a few weeks later. On opening the abdomen a quantity of ascitic fluid escaped. A smooth, thickened membrane was found lining the whole interior of the abdomen from the under surface of the diaphragm down to the pubes; it had a free border on the left side. This membrane invested most of the abdominal viscera, but the organs themselves were apparently normal.

At the Medical and Chirurgical Society Mr. Edmund Owen read a paper on erosion of joints, or, as he termed it, arthrectomy. He remarked that the operation of scraping a diseased tissue was not a new procedure, but its adoption in the treatment of pulpy or of chronic suppurative disease of a joint was comparatively recent. The construction of the hip-joint rendered it unsuitable for treatment by arthrectomy, though the latter might prove of value as a supplementary measure to resection of the head of the femur. In the case of pulpy or chronic suppurative disease of the knee-joint the operation was admirably adapted, provided the disease was not too far advanced so that the bones were extensively implicated, and that the patient was suffering neither from general tuberculosis nor albuminoid degeneration. Mr. Owen held that arthrectomy was the proper operation in most cases in which resection had hitherto been performed. It had the great advantage over resection of taking away from the articular surfaces only such tissues as were actually diseased. On several occasions it had been noticed that after the joint had been thus thoroughly cleared of elements which were of a diseased or suspicious nature the health of the patient had shown an immediate and marked improvement. The improvement which followed upon the clearing out of all diseased tissues was as marked as that which often followed the amputation of a sarcomatous limb or a scirrhous mamma.

Mr. Bryant observed that the principle of the operation was by no means new; it was that the surgeon should take away merely the diseased structure and leave the rest to take care of itself. That was a practice to which he had himself adhered for some five and twenty years. Where there was diseased bone, that part of the bone, and that only, should be removed. In the earlier days of excision it was discussed and set aside; the earlier operators took away all the structures forming the joint. Such treatment was easily applied to the knee and elbow, but not to the hip. In his own practice, in 1866, he had treated a case of chronic suppuration of the knee by scraping away the diseased bone only, and there had been excellent healing. In a case of disease of the elbow he had also removed only the head and neck of the radius and a good result had ensued, the movements of the joints being free. He had also, with good results, removed only the head of the tibia in a case of diseased knee. Mr. Macnamara said he believed the pulpy disease of the joint, so called, began in the ends of the bones, and this was an important point, for it led us to understand that the end of the bone was generally found to be greatly indurated, and required perforation either by nature or the surgeon. Mr. Barwell said the full operation of excision was wanted when the disease had begun in the bone underneath the cartilage, as by this means both bone and synovial membrane were removed. As to removing every bit of diseased tissue, he thought it would not often be possible to do so, especially if bacilli had to be sought out from all folds of the synovial membrane. In his own practice he cleared out membrane as much as bone, and drained the joint from the back. Arthrectomy might be useful, but he could not admit that it would suit all diseases of the joint. Mr. Parker said he regarded the operation as one of the most useful lately introduced, though it was not well suited as an operation on children. It was most adapted for those cases in which there was no bone disease and no sinuses, for if there were sinuses it was practically impossible to have the wound aseptic.

The last meeting of the Harveian Society was occupied with a discussion on the radical operation for hernia and its results. The subject was introduced by a paper read by Mr. Mitchell Banks, of Liverpool, in which he gave the results of 116 cases on which he had operated. In every case the operation selected had been removal of the sac and stitching together the pillars of the ring. Mr. Banks divided his cases into two groups according as they were strangulated or non-strangulated, and those under the latter heading were again arranged in two subdivisions, comprising respectively herniæ of moderate size and those which were very large (some enormous) and not capable of support by trusses. There were 59 cases of non-strangulated herniæ of moderate size, viz., ventral (double), 1; inguinal, 40 (two double); femoral, 18. Two of the inguinal cases terminated fatally, one being a man aged 47, the other a child two years of age. There were 16 cases of very large strangulated herniæ, viz., umbilical, 1; ventral, 3 (two double); inguinal, 11; femoral, 1. Four of these cases terminated fatally, viz., 3 inguinal cases and 1 femoral. The latter case ended fatally from septicæmia, and so did one of the inguinal cases. Of the other two patients 1 died from the sudden bursting into the peritoneum of an unsuspected iliac abscess after the wound had healed and the patient was walking about, the other died on the third day after the operation, which it was found impossible to complete owing to the enormous size of the hernia. There were 41 strangulated herniæ, of which 1 was umbilical, 21 inguinal, and 19 femoral. One of the inguinal cases (an old man aged 77) died from bronchitis and septicæmia, and two of the femoral cases proved fatal. As regards the permanence of the cure Mr. Banks said he had been able to follow up the subsequent history of his patients in many cases, and for periods varying from three to seven years. He had arrived at the following results: Grouping together for this purpose all the herniæ of moderate size, whether strangulated or non-strangulated, he had been able to trace for considerable periods 77 out of his hundred cases. Of these, 48 remained quite sound, 17 were only partial successes, and 12 were complete failures. Of the 16 cases of very large and enormous herniæ, he had been able to follow up 10, and of these 5 remained partially sound (though all requiring some support), 3 were partial successes, and 2 were complete failures. Mr. Banks remarked that he had gone into the matter without prejudice, but he contended that his results were in favor of the radical operation. He was not inclined to recommend operation in cases in which the hernia was non-strangulated and could be kept up by a truss. He thought the wearing of a light truss after the operation was a useful precaution. Many of his patients wore one.

A lively discussion followed the reading of Mr. Banks' paper. Mr. Bryant was inclined to caution in dealing with very large herniæ. Mr. Kendal Franks, of Dublin, was strongly in favor of the operation for radical cure, and was not inclined to restrict it to cases in which the hernia was either strangulated or could not be kept back by a truss. To athletic young men even the wearing of a truss was a drawback. He mentioned the cases of two young medical men on whom he had operated by their own request. Dr. Granville Bantock referred to his own experience, and remarked that he never employed antiseptics. Mr. Keetley advocated operating, and said he had himself employed almost every form of operation for the radical cure of hernia. He did not think that all cases in which hernia recurred some time after the operation should be put down as failures, because the tendency to hernia increased very much in later life. He referred to the value of diet (a more or less modified "Banting system") in reducing the size of some enormous herniæ. He also commented on the much greater mortality of femoral as compared with inguinal hernia, though the latter was much the more common of the two. Mr. Edmund Owen favored the operation in many cases, and referred to the case of a young athlete who had been successfully operated on by one of Mr. Owen's colleagues. He disapproved of the practice of wearing a truss after the operation, and always forbade his patients to wear one. He thought it tended to produce (by pressure) absorption of the inflammatory lymph, plugging the canal. Mr. Page uttered a word of caution against drawing too hasty conclusions as to the permanence of the cure, and said that for this reason he preferred waiting longer before publishing his own cases.

The establishment of the Army Medical Reserve continues to excite heart-burnings both among army and volunteer medical officers.

The epidemic of diphtheria in London shows no signs of abating.

OPEN-AIR TREATMENT OF PNEUMONIA; DIPHTHERITIC PNEUMONIA.

To the Editor of The Medical Record.

Sir: Dr. Gouverneur M. Smith's article on pneumonia in The Medical Record of October 20th has been successful in bringing valuable testimony to the importance of what may be called open-air treatment.

I read a paper before the Medical Society of the County of Kings in 1874, on the paramount necessity of such a plan in the management of acute febrile diseases, illustrating the subject by some cases of pneumonia and typhoid fever, including a letter from Dr. C. R. Agnew, in which he stated that in his service in the New York Hospital, during the war, he made a practice of removing out of doors those of his patients who were most seriously ill, placing their beds on the south side of the hospital, keeping them there all day, and continuing the practice into the autumn, providing each bed with a spirit-lamp and funnel, so that a stream of warm air might be thrown under the bedclothes when the weather was cool enough to require it. The immediate and the final results were very favorable. My paper was published in *The*

Sanitarian of December, 1874, at the request of Dr. Bell, the editor.

Dr. Ellsworth Elliot, in a memoir of Dr. Alonzo Clark, in the last volume of the "Transactions of the New York State Medical Association," relates that Dr. Clark, having 250 cases of typhus under his care in Bellevue Hospital, and being dissatisfied with the condition of the atmosphere, had the windows entirely removed, although it was winter—placing stoves under the open spaces and clothing the patients warmly—with a result that in a fortnight he had no deaths, while the mortality in the other wards was great.

Liebermeister says, in his article on typhoid fever in Ziemssen's "Cyclopædia," "A patient with a high temperature cannot take cold."

As to the increased mortality by pneumonia—which the reports of the Health Departments of New York and Brooklyn certainly show—I wish to suggest that there is no evidence that simple lobar pneumonia is more frequent than it was thirty years ago, or more fatal. At that time, under the rational treatment in vogue, simple, uncomplicated lobar pneumonia in the adult was very rarely fatal. I know no reason to think it is more often fatal now, under the same treatment. But the deaths by pneumonia reported of late years include not only the large number of cases supervening upon chronic diseases of other organs than the lungs, and the pneumonia of children and aged persons—which have always furnished the chief part of the fatal record—but they also include many cases of diphtheritic pneumonia, not recognized as such. I think that before long evidence will be generally accepted that the increase in the reported mortality by pneumonia is due to diphtheria of the lungs, and not to any increase in idiopathic pneumonia. This opinion is based upon observations of diphtheritic pneumonia of considerable prevalence in other parts of the country, and which further investigation will probably show to be present in some degree in this vicinity.

William Henry Thayer, M.D.

Brooklyn, N. Y., November 26, 1888.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 25, 1888, to December 1, 1888.

McClellan, Ely, Major and Surgeon. Having reported to the Division Commander, on the 23d instant, as required in Par. 15, S. O. 261, current series, A. G. O., is assigned to duty as Attending Surgeon at these headquarters, and as Examiner of Recruits at Chicago, Ill., from that date. Headquarters Department of the Missouri, Chicago, Ill., November 24, 1888.

Cronkhite, Henry M., Major and Surgeon. By direction of the Secretary of War leave of absence for two months is granted, to take effect upon his being relieved from court-martial duty at Little Rock Barracks, Ark. Par 7, S. O. 276, A. G. O., Washington, November 26, 1888.

Hoff, John Van R., Captain and Assistant Surgeon. By direction of the Secretary of War the leave of absence granted in S. O. 134, November 1, 1888, Department of the Missouri, is extended one month. Par. 3, S. O. 274, A. G. O., Washington, November 23, 1888.

Moseley, Edward B., Captain and Assistant Surgeon. By direction of the Secretary of War the leave of absence granted in S. O. 67, November 12, 1888, Division of the Pacific, is extended three months. Par. 13, S. O. 275, A. G. O., November 24, 1888.

Carter, William F., Captain and Assistant Surgeon. Leave of absence for one month is granted. Par. 4, S. O. 116, Headquarters of the Department of Texas, San Antonio, November 12, 1888.

Clendenin, Paul, First Lieutenant and Assistant Surgeon. Leave of absence for fifteen days, to take effect December 4, 1888, is granted. Par. 3, S. O. 116, Headquarters of the Department of Texas, San Antonio, November 12, 1888.

Benham, Robert B., Captain and Assistant Surgeon, Fort Laramie, Wyo. Leave of absence for one month granted. Par. 1, S. O. 111, Headquarters of the Department of the Platte, November 24, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 1, 1888.

Gaines, J. H., Surgeon. Detached from the Dolphin and ordered home.

Anderson, Frank, Passed Assistant Surgeon. Detached from the Pensacola and to the Dolphin.

Jones, William H., Surgeon. Detached from the Richmond and to the Pensacola.

Russell, A. C. H., Passed Assistant Surgeon. Detached from the Naval Academy and to the Wabash.

Drake, N. H., Passed Assistant Surgeon. Detached from the St. Mary's and to the Coast Survey.

Whitaker, H. W., Passed Assistant Surgeon. Ordered to the Nautical School-ship St. Mary's.

Lewis, D. O., Passed Assistant Surgeon. Detached from the Coast Survey and to the Naval Academy.

Wentworth, A. R., Assistant Surgeon. Ordered for examination preliminary to promotion.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 1, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	18	4
Scarlet fever	161	26
Cerebro-spinal meningitis	2	2
Measles	344	10
Diphtheria	108	42
Small-pox	2	0
Yellow fever	0	0
Cholera	0	0

Seal Rings and Antiseptic Surgery.—A correspondent sends us the following: "In these days, when one sees and hears so much about antiseptic surgery, we are apt to go into details and want to know the why and wherefore of everything connected with this most important branch of surgical practice. The writer has been attending lectures where he has been told, and it has been impressed upon him, that in all operations, no matter how trivial, he must use the greatest antiseptic precautions. He has been told that in going from the post-mortem to the operating room it is imperatively necessary, if the operation be a grave one, to change the clothing as an additional antiseptic precaution. This is eminently good teaching, and is what we should accept and practise. But what has particularly struck the writer and what called forth this communication is the fact that the very men who teach this doctrine can be seen at the operating-table, wearing the same seal rings which they had on less than five hours previously at the post-mortem table. Not one of these gentlemen would excuse the error of taking a post-mortem knife into the operating room, and yet their seal rings are just as capable and as liable to carry the micro-organism which we so much fear. We fear a wooden-handled knife in our operations, it will carry germs. We should fear our rings, they can carry germs also."

Lanolin and Boric Acid.—Dr. Russell Sturgis, Boston, Mass., writes: "Will you allow me to correct through your columns a statement made by the *British Medical Journal* which is copied by you on page 542, issue of November 3, 1888. In referring to an article by me on the use of lanolin and boric acid, I am stated as using an ointment composed of thirty per cent. lanolin and eight per cent. boracic or boric acid. What I do use is lanolin, ℥ j.; boric acid. ʒ j.; or eighty per cent. lanolin, boric acid, twenty per cent."

The Late Dr. Henry B. Sands.—At the last meeting of the New York Pathological Society the following preamble and resolutions were adopted:

Whereas, Dr. Henry B. Sands was a most highly esteemed member of the New York Pathological Society for more than thirty years, and was considered worthy of being its president when he was only thirty-six years old. And

Whereas, He was a devoted and successful student of pathology all the days of his professional life, had long stood in the very foremost rank of the greatest and best of surgeons, was a learned professor and a brilliant lecturer, a wise physician and a trusty counsellor; to all of which positions he had attained unassisted, solely by his own industry, ability, and integrity. And

Whereas, He was a truly genial and benevolent man, a pleasant friend, and a sincere Christian;

Therefore, We sorrow for ourselves and our profession, which has suddenly sustained so great a loss in his untimely death; we will cherish his memory among those of our most illustrious dead and hand down the remembrance of it undimmed to our successors.

"We sympathize sincerely with his desolate family, but remind them of the inestimable value of his good and honorable record and assure them that the name of Sands will long be held in glory and honor among physicians and surgeons.

Resolved, That the foregoing be incorporated in the minutes of this Society and that a copy thereof, duly authenticated, be sent to his family.

(Signed) John C. Peters, M.D.,
Elsworth Eliot, M.D.,
Louis A. Sayre, M.D.

Shakespeare and the Pia Mater.—Dr. B. W. Richardson writes to *The Lancet*: "The mode in which William Shakespeare obtained his knowledge about the pia mater is, I think, fairly explainable from a curious literary discovery which I was so fortunate as to drop upon, in my readings, a few months ago. I came across a large volume of anatomy published in the year 1615 by Helkiah Crooke. It may be said without hesitation that this compendious volume was the first great work in anatomy ever published in the English tongue. It fills 1,111 pages of imperial-quarto size, closely printed, and it is illustrated throughout by drawings on wood of anatomical subjects. Such a book would cost the most industrious writer, even in these days, several years to compile and bring out, and I should think did cost at least fifteen to twenty years of labor. It contains not only anatomy pure and simple, but various passages of a physiological and psychological nature which had descended from Aristotle and Galen, with references also to the Pythagorean controversies and other subjects of metaphysical cast. The book is one we may speak well of, although it is really nothing more than an industrious compilation from Gasper Bauhinus and Andreas Laurentius; and, in so far as the plates are concerned, from Vesalius out and out, being, in point of fact, a kind of new edition of the anatomical compendium of Germinus which that systematic plagiarist from Vesalius printed, published, and dedicated to Queen Elizabeth in the year 1559. In the volume of Crooke the membranes of the brain are well defined and described, the pia mater takes a very distinct place, and the brain and cerebro-spinal system are figured with a clearness which would excite no small degree of wonder in one who for the first time studied them even in this day. What connection has the book of anatomy by Helkiah Crooke with the plays of Shakespeare? This remarkable connection: that the man who printed the works of Crooke was W. Jaggard, of the Barbican in London, the same man who was the printer for Shakespeare. Within easiest walking distance from the Globe Theatre, the scene of the great William's managerial glory, was the printing-office of Jaggard, where the plates and letter-press of Crooke would for long seasons be the most remarkable press-works of the time. To that office the indefatigable playwright would often be drawn by his own business, and there he would hardly fail to see unfolded before him the anatomy of man from a sure source, and just in the form that would most readily appeal to his ever-absorbing mind. In this school of anatomy, ready prepared for his hand, our immortal dramatist learned, as I believe, the fact of the existence of the pia mater, saw the drawing of it, and learned the function of it as the feeding mother of the brain. I might go a long way further in exposition of the source of Shakespeare's anatomical knowledge generally, for the closer this book of anatomy and the book of plays are read together the more clearly it is detected where and how the dramatist became the student of anatomy. But at this moment I am content to stop with the proposition placed before the reader, that the pia-mater argument of Shakespeare was simply derived from the work and plates of his industrious contemporary, Helkiah Crooke, 'doctor of physic, physitian to his Majesty and his Highness, and professor in anatomy and chirurgery.'"

The Question of Recurrence of Malignant Tumors.—Dr. Verneuil strongly favors medicinal treatment after the excision of malignant growths, while the morbid process is in abeyance, and advises a prolonged course of alkaline medication, such as may be obtained by the use of Vichy water, magnesia, etc., together with arsenic, with a view of neutralizing the gouty diathesis, which he believes to be the predisposing cause of cancer. Dr. Mollière, of Lyons, thinks that the great point to attend to in estimating the probability of recurrence is the patient's age. If he be young, the disease is so certain to return that he doubts if it is worth while to operate; after fifty there is a fair chance that recurrence may not take place; after seventy it is almost certain that the patient will remain free from the disease.—Quoted by Dr. Gouley, in *New York Medical Journal*.

Hysteria in a Mare.—Bay mare, about fourteen years, partly cob bred; used for light carriage work. She is ordinarily quiet, but for some months at her horsing period she becomes absolutely unmanageable. She kicks and bites in the stall, destroying all the wood-work. The entrance of anyone or any sudden noise starts her up into a paroxysm of mixed rage and fear. The harness is put on with difficulty; when harnessed she may drive quietly for a time, but with any unusual sight, or with no apparent cause, she will have attacks similar to those in the stable. At the end of a few days the trouble disappears for a variable period of several weeks. Examination of uterus and ovaries showed no abnormal condition. Treatment with large doses of asafœtida, ʒ iij., several times daily), commenced with the first symptom, allayed the trouble: but, when omitted, they returned with old everity. The case was lost sight of after six months.—Dr. Huidekoper, *Journal of Comparative Medicine*.

Urine as an Emetic.—Dr. F. J. Hutton, of Fergus Falls, Minn., writes: "About one year ago Mrs. Charles R—— asked me the following question: 'Do you know, doctor, that urine-of-lye is the best thing in the world for croup ?' I replied that I was not aware of the fact, and forthwith solicited details—what was the urine-of-lye, and how did she administer it ? She answered, volubly enough, that urine-of-lye was composed of equal parts of urine and sirup; and that her three children, now living and well, would have died of croup many a time if it had not been for this golden remedy. She administered it by the mouth, half a teacupful at a time, whenever the children got croupy, and it vomited them so quickly and so well they got well right away. I had no good reason to suppose that Mrs. R—— was consciously and deliberately lying, but that an element of the white-lie order had crept into her narrative seemed highly probable. I therefore determined to test this thing for myself, and have done so several times since, and am pleased to be able to fully corroborate her statement that urine is an excellent emetic. My experiments were made on rural urchins whose stomachs are not over finicky. Ignorant of its composition, they knew the remedy to be unpalatable, but were induced to quaff it on various sweetmeat and pecuniary considerations. It does seem late in the day to advocate such crude and barbarous therapy, and yet it requires no strain of imagination to conjure up cases and circumstances in which, to-day, the use of this remedy would save life as this woman declared. Grant that a prompt and powerful emetic is needed, and that there is none other at hand, and the urine-of-lye is not an idle fable."

PARALYSIS PENIS IN A GELDING.—Black gelding, six years old, coach-horse. Was purchased three months previously. Penis has been gradually dropping, until it hangs from the sheath most of the time. No cause can be discovered, except a tumor on the cord of the testicle—off side—the near cord is very long and fastened to the cicatrix. Cast and removed a fibroma the size of a lemon. Recovery.—DR. HUIDEKOPER, *Journal of Comparative Medicine.*

A PERPLEXINGLY UNCERTAIN FEE.—Dr. Benjamin J. Baldwin, of Montgomery, Ala., writes: The Trojan war, celebrated in the songs of Homer, appears in Greek antiquity as a luminous point in the midst of profound darkness. Before this memorable expedition, and for a long time afterward, the history of medicine rests on uncertain traditions often mingled with interesting fables.

Coming on down through the unending lane of medical history, we find many amusing incidents recorded in the pages of our early writers.

Certainly there is no more pleasing picture than that of the old village-doctor sitting on his horse in the streets of the village, prescribing for the congregated community. Simple in dress and manner, yet self-important and proud in the eyes of himself and patients, he was monarch of the field, and wielded an influence felt throughout the neighborhood, and second only to the priest's.

Can you not see him as he sits in the saddle before the door of the squire, where all the headaches, side aches, backaches, and toothaches have come to consult him ?

First comes the old man holding his arm to have his pulse counted; then the incorrigible boy, with his jaw tied up, on the back of his larger brother; pushing to the front is the anxious mother leading her timid daughter; while standing in the background is seen the fat and jolly middle-aged farmer drinking the health of his less fortunate neighbors.

Off by the hay-stack stands the eldest son, guarding the doctor's fees. The first patient has brought a fat Berkshire pig, the next some home made tobacco and dried beef, and here and there may be seen a jug of molasses, a dried skin, a pair of buck-horns, and a barrel of apple-cider.

Ah ! who could have been more independent ?

Why, the autocrat of Regent's Park could not be more *absolute* than was this honored and rare old village-doctor.

Now, while the fees of the modern doctor are of a less miscellaneous and domestic nature, yet they are sometimes just as unique. I am going to tell the wealthy doctors of Murray Hill, who know little of the oddities of the practice of medicine in smaller and less wealthy places than Gotham, of a rare visit and extraordinary fee which was offered me in Montgomery not long ago.

There came to consult me a man from the "Piny Woods." He was plain, honest, candid, and rural. A jeans coat, home-spun hickory-shirt, red copperas breeches, and long straggling hair constituted his make-up. He entered without ceremony, and made known his wants at once.

"Doc, I'se hearn tell that you fix people's years," he said.

I remarked that I confined my practice to the eye, ear, and throat.

"Well," said he, "I've been er gitting deefer an' deefer for now guine on fore yeer, and I hearn that broth' Josiah Sykes had his years fixed up by you, and I come all the way from Pike to see ye."

I asked him to sit down, and said that I would examine him and tell him what I could do. Upon examination I found both ears tightly packed with wax. I told him I thought I could relieve him, and, after saturating the wax with sweet-oil, the *excavation* and *dislodgement* began. An enormous amount of wax was gotten off each ear.

The old fellow saw it and to him it was incredible.

"Doc, you didn't git all that thar corription outen my head, did ye ?" I replied that I did.

"Well, by grannie, if you don't lay o'er anything I ever seen in Pike, I gin it up."

After such an effusive compliment, of course, I felt better. *It had been a great operation.*

"Now, doc, how much is ye guine to tax me ?" he said.

"Oh, I hardly know what to charge you," I replied, seeing he was very limited in means.

"Well, doc, if I had a thousand dollars I'd make ye rich. I ain't got much, but I'll do my bess."

"Never mind about that, it's all right, you can pay me some other time."

"No, doc, I muss pay ye. *Here's a dollar, but touch 'er light, I've got to git back home on the train.*"

The fare was sixty-five cents.

A VICTIM TO WATER.—A bulky tomb in the form of a dwelling-house is the monument to "Dame Mary Page," relict of Sir Gregory Page, Baronet. Her epitaph relates in four lines that

In sixty-seven months she was tap'd sixty-six times.
Had taken away 240 gallons of water
Without ever repining at her case
Or ever fearing the operation.

She died in 1728, in the fifty-sixth year of her age.—*Pall Mall Gazette.*

THE TREATMENT OF UTERINE COUGH.—According to M. Chéron certain functional and organic lesions of the utero-ovarian apparatus sometimes give rise to a dry, irritating cough, not to be explained by the condition of the lungs or throat. This symptom readily yields to the valerianates. If the cough be associated with derangement of the cerebral circulation—flushes of heat, vertigo, etc., the best drug is the valerianate of quinine in the following form: ℞. Valerianate of quinine, 1 gramme; sirup, 40 grammes; infusion of black coffee, 120 grammes. Two or three tablespoonfuls to be taken half an hour before or two hours after meals. If the cough be troublesome only at night or shows a tendency to periodicity, the same drug is of benefit: ℞. Quininæ valerianatis, 1 gramme; ext. cinchonæ, q. s.; fiat 20 pilulæ. One before each meal.

A REMEDY FOR TAPE-WORMS.—Bernard Persh has obtained excellent results in the treatment of tape-worm by the aid of the following formula: ℞. Ol. crotonis, gtt.j.; chloroform, ʒ j.; glycerini, ℥ j. This dose is taken on an empty stomach in the early morning without any preliminary preparation. It is not disagreeable to take, and operates very promptly.

Ointment for Obstinate Acne.—℞. Resorcine, 3 to 5 grammes; powdered starch, 5 grammes; oxide of zinc, 5 grammes; vaseline, 15 grammes. Apply this ointment on going to bed, and rub it off in the morning with olive-oil and wadding. It never gives rise to irritation, and its effects begin to be felt within three days. Incidentally one may recall the proverb *matrimonio curat varus—varus*, in this case, being acne. At the same time the patient should abstain from beer, wine, liqueurs, and fatty food.

The Treatment of Fetid Sweats.—For fetid sweating of the feet, Dr. Bardet recommends washing the feet at least once daily, following it up with frictions with alcohol. The stockings to be changed daily, sprinkling them with a small quantity of a powder containing: Talc, 40 parts; trinitrate of bismuth, 45; permanganate of potassium, 13; salicylate of sodium, 2. Misce. When the objectionable perspiration is general, the body should be powdered with ℞. Rice-powder, 60 parts; subnitrate of bismuth, 15; permanganate of potassium, 10; talc, 5. Misce

The Treatment of Dysmenorrhœa.—For young girls Dr. Goubert prescribes: Iodoform, ½ grain; ext. belladonna, ⅙ grain; asafœtidæ, 1⅓ grain. In pill form. Beginning six or eight days before the time of menstruation, six pills should be taken daily. For adult women he prescribes: Potass. iodid., ʒ j.; tinct. croci, ʒ ij.; tinct. belladonna, ʒ vj.; syrup. aurant. cort., ad. ℥ vj. Dose, a tablespoonful morning and evening, in any convenient liquid, for a week preceding menstruation.

Unglazed Tissue-paper as a Surgical Dressing.—According to Dr. Bedoin unglazed tissue-paper, such as is used in making cigarettes, is useful in the form of compresses composed of one or several double sheets, as bandages, or in very fine shavings in the form of lint. Applied in this manner it has the same effect as gauze, and is much less expensive. It may be used with all antiseptics either in a dry or moist state. In the latter case the paper is dipped into the antiseptic solution, or merely into pure water when the spray is not employed. In ordinary dressings this paper is an excellent medium for most antiseptic remedies which were formerly applied by means of compresses or lint in the form of ointments or solutions. Thus dressings of this paper may be prepared beforehand with morphine, belladonna, cocaine, iodine, etc., with the greatest facility. The application of these dressings has been attended with excellent results in the most varied surgical affections. Comparative experiments have shown that the hydrophile property possessed by paper lint is one-third greater than that of thread lint. It is absolutely necessary to cover the dressing with an impermeable outer covering like mackintosh, to prevent the edges of the paper beyond the borders of the wound from stiffening.—*L'Union Médicale.*

What the Antiseptic Midwife should have Ready.—Dr. Clement Godson states that, when engaged to attend a patient in labor, he orders the following to be ready in the house: 1. Chloroform, ʒ ij., placed in a stoppered and capped bottle. 2. Extracti ergotæ liquidi, ʒ j. Dose, teaspoonful in a half wineglass of water. 3. Acidi carbolici, ℥ j.; adipis benzoate, ℥ ijss., mix and make into an ointment to be labelled carbolized cream. This is always to be used in making vaginal examinations, but I also order a pot of ordinary. 4. Vaseline—which I use freely when the child's head is on the perineum, externally as well as internally. If the carbolized cream is used for this purpose the patient is sure to complain severely of burning and smarting in the passage after delivery. 5. A tube of corrosive sublimate. 6. A three-pint douche-can. 7. A half gallon glass-stoppered bottle, empty, labelled "corrosive sublimate solution, 1 to 1,000," to be used with an equal part of hot water as a lotion. 8. An eight-ounce bottle of carbolic acid, liquefied, labelled: "To make, with a gallon of water, a lotion of 1 to 20." The author goes on to say: "I am strongly of the opinion that midwifery should be more in the hands of midwives and less in the charge of medical men. The loss of time in watching the first stage of labor is deplorable. One woman may unnecessarily absorb the whole attention of a busy doctor when the lives of others may be sacrificed by his absence. On the occasion of the birth of George IV., the queen was delivered by Mrs. Stevens. Queen Victoria was brought into the world by a midwife, as were all the children of George III."

Absence of the Uterus.—Dr. R. Milbret-Damskaya reports a case of this rare defect in *Vratch*, No. XXXIX., 1888. A woman, twenty-seven years of age, applied to her for the relief of a chronic dyspepsia. In the course of the examination it was learned that she had never had any menstrual flow, although its absence seemed to cause her no inconvenience. She had been married seven years. She stated that she had sexual desires, but coition was somewhat painful and was productive of no pleasure, although it gave satisfaction to the husband. She was below the medium height, but well developed, and of a wholly feminine appearance. The external genitals were normal in appearance, but the vagina was shallow and terminated in a cul-de-sac a short distance above the hymen. A most careful examination failed to detect the existence of a uterus. In the normal situation of the ovaries were two very soft bodies, insensitive to pressure, of the shape of the ovaries but somewhat larger. The woman was examined repeatedly by several different observers, and all failed to discover any body which could be taken for the uterus.

A Peculiar Case of Intestinal Invagination.—Dr. Felice Ibba is the authority for the following case, which he reports in *Il Raccoglitore Medico* of October 10 and 20, 1888: A woman, forty years of age, gave birth to a well-developed child at term. Soon after the termination of labor the woman began to complain of atrocious pains in the abdomen, her temperature rose to 106.8° F., and she vomited a little. Her condition remained about the same for six days and then began rapidly to improve, so that she was soon out of bed and walking about Four or five days later, while at stool, she passed a piece of the small intestine, fourteen inches in length, containing about a hundred grape-seeds and the undigested portion of some other fruit which she had eaten the day before her child was born. A few days later she ate freely of melons and suffered a return of pain, vomiting, and fever, but was soon up again and attending to her household duties. Once more she partook of a great quantity of watermelon, and died in consequence of her indiscretion four weeks after the birth of her child. At the autopsy it was found that invagination had occurred at a point about twelve inches from the pylorus. The invaginated portion had sloughed away, leaving, however, enough of the upper end telescoped in the lower to prevent any escape of fecal matter into the peritoneal cavity. This had finally slipped out and about a quart of the contents had passed into the abdominal cavity. A large part of this matter consisted of the seeds of watermelons and grapes.

Opium-smoking.—The English colonial physician in Hong Kong refers in his last annual report to the opium-smoking habit among the Chinese, and holds that it is hardly worse in its effects, when used in moderation, than tobacco-smoking: The sudden abstraction of opium from those accustomed to smoke it causes no special physical disturbance. He has seen numbers of hearty old men who had smoked opium all their lives, yet were in good flesh and strength, enjoyed a fine appetite, and slept the sleep of the just. He maintains that the injurious effects of this habit are not to be compared with those of the abuse of alcohol.

Dextrocardia.—In the report of a case of dextrocardia by Dr. Michel, on page 479, the area of "heart dulness" is referred to as merging into "line dulness." This should read "liver dulness."

A NEW METHOD OF TREATING CONSUMPTION BY INHALATIONS OF HOT DRY AIR.

By LOUIS WEIGERT, M.D.,

BERLIN, GERMANY.

THE indisputable fact that the temperature optimum for tubercular bacteria is 37.5° C., and that higher or lower degrees of heat hinder or entirely destroy their capacity for development and propagation, has led me to make experiments the results of which I have briefly embodied in the following:

When in rooms the temperature of which averages about 20° C., air heated to 150° C. is inhaled, the temperature of the body rises about $\frac{1}{2}$° to 1° C. within a few minutes, returning to its normal degree in about one hour after such inhalations; at the same time the number of respirations is decreased, the decrease being the greater the greater the frequency of respiration was prior to the inhalation; the inspirations become deeper, the pulse is accelerated slightly and only during the first few minutes the temperature of the exhaled air rises to at least 45° C.

These inhalations, when taken by consumptives, produce the following effects:

1. The removal of dyspnœa. 2. Decrease of coughing spells. 3. During the inhalations, more especially within the first few days, increased expectoration; later on, a remarkable decrease of the same. 4. Increase of appetite. 5. Increase of bodily strength. 6. In most cases a complete cessation of the acute process within a short time. 7. Removal of catarrhal symptoms. 8. Clearing up of previously infiltrated parts. 9. Disappearance of bronchiectasis. 10. Cicatrization of cavities.

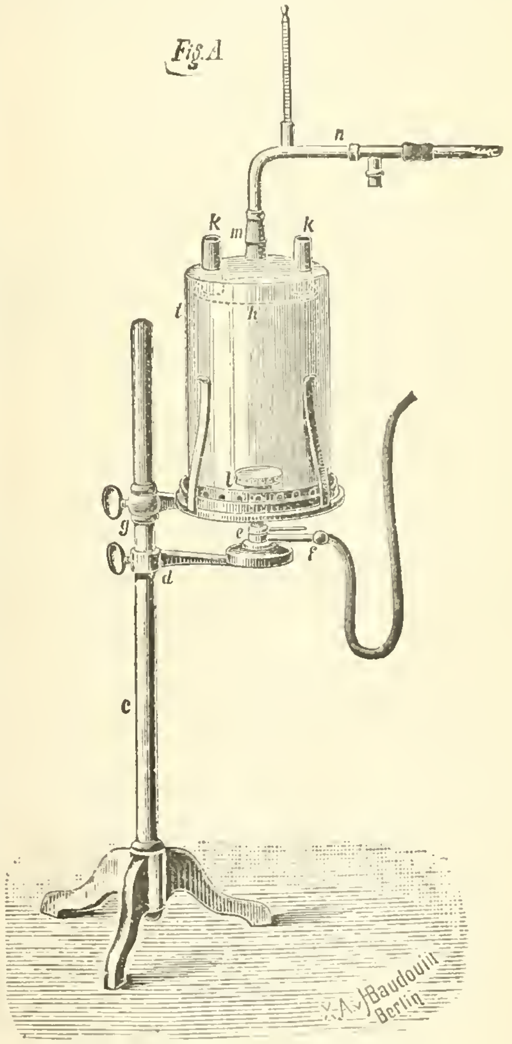
The following is a description of the apparatus which I have caused to be constructed for the purpose of these inhalations:

Figure *A* shows the apparatus *in toto*. It consists of stand with burner; heating cylinders; inhalation-tube with mouth-piece.

The stand (*c*), made of galvanized iron, consists of a slim rod, affixed to a tripod; to this rod a movable support (*g*) is attached by a screw with three steel springs holding the apparatus in place. Below this, movable by means of a screw, is a small plate carrying the burner (*e*), either one of Bunsen's gas-burners on a spirit-lamp with a "*mitrailleuse*" burner (eight or ten small nicks in a circle) being employed. In case the gas-burner is used, a rubber tubing (*f*) connects it with the gas.

The heating cylinders are made of copper, the inner one (*h*) having on its lower edge a rim upon which the outer one, which has a cover of asbestos, rests. The inner one has two small funnels (*k*, *k*) serving as vents and penetrating the outer cylinder. The air, entering through the small air-holes (*l*) in the rim of the outer cylinder, becomes heated by passing through the interspace between the walls of both cylinders, and is then drawn through the tube (*m*) of the outside cylinder into the inhalation-tube (*n*).

Figure *B* shows the inhalation-tube with mouth-piece. The tube is made of copper and consists of the main tube (*o*), into which the small tube (*q*) intended to hold the thermometer (*p*), fastened by a well-fitting cork, is affixed. In the main tube (at *r*) there is a valve (*s*) made of aluminium. At *t*, another small tube is fitted in containing the aluminium valve (*u*). A hard-rubber mouth-piece is fastened to the end of the tube at *w*, which, in case of complaints being made by the patient of objectionable rubber taste, is lined with aluminium. The small rods *x*, *x* serve to keep the valves in place, which, during respiratory action, alternately open and close, so that the air inhaled through the main tube (*o*) is exhaled through the small tube *t*.

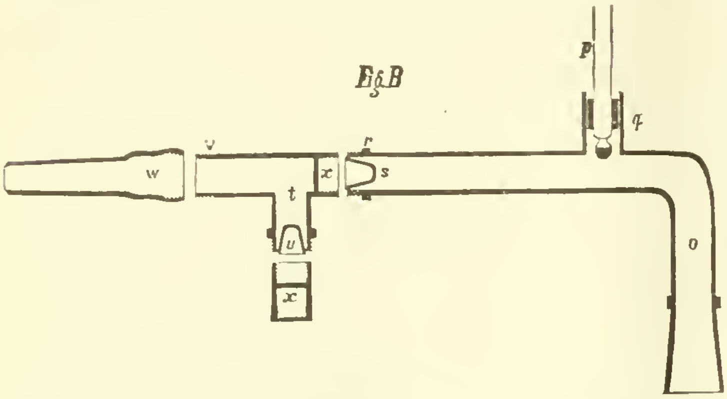


For the use of patients too weak to inhale while seated, the inhalation-tubes are differently constructed; either the mouth-piece is connected with the tube by means of a flexible tubing about ten inches in length, or the entire tube has a curved elongation long enough to reach into the mouth of the patient resting on a couch or lying abed. The temperature of the air inhaled through these elongated tubes is 25° F. less than through the ordinary tubes. To avoid the discomfort caused to patients by the heat from the cylinders, I use a movable screen of sheet-iron which surrounds the apparatus and to which a small reading-desk is fastened. My experience proves that the use of the apparatus is most efficacious if the following directions are observed:

1. The duration of the inhalations, at first half an hour twice daily, must be extended gradually, but as quickly as possible, to two hours twice daily or more; the quicker or slower increase, or the decrease of the same, is to be determined upon by the attending physician according to the patient's condition. With many patients, long sittings do not agree, whereas short ones have a beneficial effect; in other cases it is necessary to extend the time of inhalation to six hours a day before an improvement takes place.

2. The patient is to be instructed to take deep, and even forced, inspirations.

3. The temperature of the heated air inhaled, beginning with 100° C., is to be raised as quickly as possible to 250° C., which can easily be done within two or three days without any discomfort to the patient. The degrees given above refer to the temperature indicated by the thermometer inserted into the tube. As the valves do not close hermetically, they allow some of the outside air to pass into the tubes, so that the temperature of the air inhaled, shown by the thermometer to be, say, 250° C., is actually only about 160° C.



4. In case of hæmoptoë the inhalations are to be interrupted for a few days.

5. In case of hæmoptysis they are to be continued, but with the proviso that the inspirations be only superficial.

6. Should attacks of pleurisy set in, same directions as in No. 4 hold good.

7. After each sitting the patient must remain in-doors for at least half an hour; not until then, and only in fair weather, ought the patient to be permitted and prevailed upon to take out-door exercise.

As a matter of course, this treatment does not exclude the use of any other therapeutic agents, whenever they are indicated; as, for instance, antipyretics, alcoholics, etc. In consideration of the fact that by means of these inhalations we merely render the conditions for the development of the tubercular bacteria less favorable, and that only for the time of the inhalations, it is evident that the cure can only be a gradual one.

Out of the number of cases treated in accordance with my method, I cite the following as illustrating the results of the treatment:

I. K——, aged twenty-seven, glazier; no hereditary taint; sick since 1881; since then several attacks of hæmoptysis every year, the last one taking place the end of last May. Came under treatment June 7, 1888. *Status præsens:* Marked cachexia, great debility, evident dyspnœa. Physical signs, right anterior region: Flatness on percussion down to the fourth intercostal space; bronchial respiration, with plentiful subcrepitant râles over the entire lung in the supraclavicular region with amphoric intonation. Left anterior region: Dulness on percussion in the supraclavicular region; bronchial respiration with plentiful subcrepitant râles over the entire lung. Right posterior region: Dulness on percussion over the entire lung, absolute flatness between the second and fifth ribs; respiratory murmur not audible from the second to the fifth ribs; over the rest of the lung, weak bronchial respiration; over the lower lobe, pleuritic friction murmur. Left posterior region: Dulness on percussion in the fossa suprascapularis; plentiful subcrepitant râles over the superior lobe.

Status of same, November 5, 1888. Patient feels perfectly well; had last attack of hæmoptysis August 19th; breathing upon bodily exertion somewhat rapid, but normal in rest. Physical signs, right anterior region: Percussion sound normal, only in the supra- and infra-clavicular region somewhat shortened; bronchial respiration in the supra- and infra-clavicular regions without râles. Left anterior region: Normal percussion sound; vesicular respiration. Right posterior region: Normal percussion sound down to the fifth intercostal space—from there on to the seventh rib, dulness on percussion; vesicular breathing with but few subcrepitant râles down to the fifth rib; from there to the seventh rib, weak respiratory murmur with but few subcrepitant râles, heard only during deep inspirations, and pleuritic friction murmur. Left posterior region: Normal percussion sound down to the third rib; vesicular respiration with sharp and prolonged expiration sound without râles; over the other parts, loud vesicular respiration.

O. W——, aged eighteen, apprentice, hereditary taint, sick since November, 1886; repeated attacks of hæmoptysis every year since. Came under treatment August 1, 1888. Physical signs: Great emaciation, costo-abdominal breathing; number of respirations, 45; pulse, 104. Right anterior region: Normal percussion sound, only somewhat shortened down to the third rib. In the superior lobe, weak, jerking respiratory murmur; elsewhere, weak, vesicular respiration. Left anterior region: Flatness on percussion down to the fourth rib; down to the fourth rib, loud bronchial respiration above the clavicula with amphoric intonation and bronchophony and subcrepitant râles. From the fourth rib downward, very weak broncho-vesicular respiration with some pleuritic friction murmur. Right posterior region: Percussion sound normal, somewhat shortened only in the suprascapular region. Feeble broncho-vesicular respiration, with a few crepitant râles down to the fourth rib; elsewhere, feeble vesicular respiration. Left posterior region: Flatness on percussion down to the sixth intercostal space; weak bronchial respiration with many subcrepitant râles within the limits of the flat percussion; elsewhere, weak vesicular respiration. Status of same on November 5, 1888: Quiet respiration; pulse, 90; increase in weight, eight pounds. Physical signs, right anterior region: Normal percussion sound, only somewhat shortened above and just below the clavicula, over the superior lobe somewhat sharpened vesicular respiration, being, over some few spots, slightly jerking, with very few subcrepitant râles, audible only in deep inspiration. Left anterior region: Flatness on percussion down to the fourth intercostal space; down to the fourth rib, low, weak respiratory murmur with subcrepitant râles; elsewhere vesicular respiration; in the axillary region, weak respiratory murmurs. Right posterior region: Normal percussion sound; everywhere vesicular respiration; down to the third rib, few subcrepitant râles. Left posterior region: Dulness on percussion down to the fourth rib, only in the suprascapular region flatness on percussion; within those limits weak bronchial respiration with but few subcrepitant râles; in the sixth intercostal space very weak pleuritic friction murmur.

D. B——, aged thirty-eight, merchant; no hereditary taint; sick since February, 1888; profuse hæmoptysis in March, 1888; since then repeated attacks of hæmoptysis. Came under treatment August 28, 1888. Physical signs, paralytic thorax; respiration abdominal; during the respiratory action the left lung is less active than the right. Right anterior region: Flatness on percussion down to the sixth rib; the liver-dulness begins at the sixth rib and extends to the arcus costarum. Down to the sixth rib loud bronchial respiration; above the clavicula bronchophony; below the sixth rib weak respiratory murmurs. Left anterior region: Above the clavicula percussion sound somewhat shortened; above the clavicula bronchial respiration with crepitant râles; below the clavicula down to the fourth rib, weak respiratory murmurs with crepitant râles; from the fourth rib downward weak vesicular respiration. Status of same, November 5, 1888: Normal respiratory action. Right anterior region: Moderately marked dulness on percussion over the supraclavicular region; over the clavicula, somewhat shorter percussion sound; above and below the clavicula, strong respiratory murmur, with bronchial expiratory sound and but very few subcrepitant râles; elsewhere vesicular respiration. Left anterior region: Normal percussion sound; in the supraclavicular region, weak broncho-vesicular respiration with few crepitant râles; below the clavicula, vesicular respiration with prolonged expiratory murmur; otherwise weak vesicular respiration. Right posterior region: Moderate dulness on percussion down to the fifth rib; within those limits loud bronchial respiration without râles; elsewhere weak vesicular respiration. Left posterior region: Normal sound on percussion, shortened only in the fossa suprascapularis; weak bronchial respiration with subcrepitant râles in the fossa suprascapularis; otherwise vesicular respiration everywhere.

C——, aged thirty-eight, joiner; no hereditary taint; sick since 1875, hæmoptysis, August, 1876; since frequently repeated. Came under treatment September 26, 1888. Physical signs: Thorax paralyticus. Right anterior region: Dulness on percussion over the entire lung. Over the superior lobe bronchial respiration, below the clavicula, with amphoric intonation and subcrepitant râles; in the inferior lobe, bronchial respiration with pleuritic friction murmur. Right posterior region: Dulness on percussion down to the seventh rib; weak bronchial respiration without râles. Left anterior region: Dulness on percussion down to the third rib; within these limits broncho-vesicular respiration; elsewhere vesicular respiration. Left posterior region: Normal percussion sound, shorter only in the suprascapular region; auscultatory signs as in left anterior region. Status of same on November 5, 1888. Right anterior region: Moderately marked dulness down to the fourth intercostal space; in the fourth intercostal space somewhat shortened on percussion sound; in the supra- and infra-clavicular regions, broncho-vesicular respiration with sharp and prolonged expiratory murmur and subcrepitant râles; otherwise vesicular respiration everywhere. Left anterior region: Shortened percussion sound down to the third rib; above the clavicula, without resistance or palpatory percussion; in the axillary region, on both sides, loud, full percussion sound; vesicular respiration everywhere. Right posterior region: Moderate dulness on percussion down to third rib; shortened percussion sound from there downward to fifth rib; over the superior lobe, weak bronchial respiration; from the third rib downward, vesicular respiration. Left posterior region: Normal percussion sound; vesicular respiration everywhere.

O. P——, aged sixteen, page; no hereditary taint. Pleuro-pneumonia in 1884; pleurisy in March, 1888. Since then dyspnœa. Entered treatment, October 10, 1888. Physical signs: At present, feverish condition. Dyspnœic costo-abdominal respiration. Slight built; thorax moderately well formed, the latitudinal diameter being greater in its lower portion. With every inspiration the intercostal muscles of the sixth, seventh, eighth, and ninth intercostal spaces are put into action, the thorax being drawn at the same time upward and backward. The heart choc is plainest in the parasternal line in the left fourth intercostal space. Right anterior region: Flatness on percussion down to the fourth intercostal space; down to the fourth rib loud bronchial respiration, with weak bronchophony and very many subcrepitant râles; from the fourth rib, loud bronchial respiration with weak bronchophony and very many subcrepitant râles; from the fourth rib downward, vesicular respiration with but few subcrepitant râles. Left anterior region: Flatness on percussion down to the seventh intercostal space; down to the third rib loud bronchial respiration; from there downward weak bronchial respiration, subcrepitant râles over the entire lungs. Right posterior region: Flatness down to the fifth intercostal space, loud bronchial respiration with many subcrepitant râles, and loud bronchophony down to the fifth intercostal space. Left posterior region: Flatness down to the sixth intercostal space; in the fossa infraspinata, bronchial respiration with amphoric intonation and very many subcrepitant râles; over the rest of the lung weak bronchial respiration with but few subcrepitant râles. Status of same, November 5, 1888. Respiration somewhat accelerated, temperature normal; pulse, 120. Right anterior region: Flatness in the fossa supra- and infra-clavicularis; loud bronchial respiration with many subcrepitant râles over the same region; over the rest of the lung weak bronchial respiration with but few râles, and pleuritic friction murmur. Left anterior region: Flatness down to the sixth rib; in the axillary region normal percussion sound, bronchial respiration down to the third rib; from there downward weak broncho-vesicular respiration without râles; in the axillary region, vesicular respiration with but few râles. Right posterior region: Flatness down to the third rib; sharp bronchial respiration in the fossa supra-scapularis; loud bronchial respiration in the first, second, and third intercostal spaces; in the fourth, fifth, and sixth intercostal spaces loud bronchophony. Left posterior region: Flatness on percussion down to the fourth rib; bronchial respiration with many crepitant râles in the first three intercostal spaces; over the rest of the lung sharp vesicular respiration without crepitant râles.

CLINICAL NOTES ON ELECTRO-THERAPEUTICS.

By PASSED ASSISTANT SURGEON C. H. H. HALL, U. S. NAVY.

U. S. NAVAL HOSPITAL, YOKOHAMA, JAPAN.

The growing importance of electricity as a remedial agent may warrant the publication of the following results of its use. The cases are grouped according to their nature, and as the point of view is exclusively therapeutical, all unnecessary details are omitted for the sake of brevity.

ARTICULAR DISEASES. CASE I.—Rheumatic synovitis of the right knee-joint. Redness, swelling, and pain upon movement after a various treatment of two months' duration.

July 22d.—Placed an electrode, 1.77 sq. in., upon each side of the joint, and passed a galvanic current of five milliampères through the parts for fifteen minutes. Daily treatment.

July 31st.—Redness and swelling gone, pain much abated. Treatment continued.

August 6th.—No pain upon locomotion.

August 20th.—All symptoms absent since last note. On duty as orderly during four hours a day, going up and down stairs frequently. No treatment.

September 1st.—No return of symptoms.

CASE II.—Gonorrhœal rheumatism of five weeks' duration affecting left knee and both ankle-joints, which are much swollen and painful upon pressure and locomotion. No constitutional disturbance.

July 15th.—After a trial with ol. gaultheriæ, acid. salicylic., etc., without improvement, an electrode, 1.77 sq. in., was applied to opposite sides of each joint in turn, and a galvanic current of three milliampères passed for five minutes. Daily treatment.

July 21st.—Puffy swelling about the patella has quite subsided; no pain in the knee except upon locomotion. Ankles less swollen, but still tender. Treatment continued.

July 29th.—No pain in knee upon locomotion; slight hard swelling over the inner tuberosity of the tibia. Has a little swelling at the ankles and slight discomfort upon walking. Galvanism continued.

August 10th.—Goes about without discomfort. Knee looks well, but left ankle swells a little after use.

August 15th.—Virtually well, all symptoms gone.

Case III.—Gonorrhœal rheumatism in right ankle and instep, of four months' duration. The affected parts are tensely swollen, hot, and very tender. No constitutional disturbance except debility. Treated with alkalies, ol. gaultheriæ, acid. salicylic., etc., without benefit.

July 15th.—With the anode upon the instep and cathode in the palm of the hand, electrode 1.77 sq. in., passed a galvanic current of two milliampères for five minutes.

July 24th.—Pain and swelling noticeably diminished, no redness, and the foot can be shifted with less discomfort. Treatment continued.

August 1st.—Swelling about the same; no pain except upon movement of the foot. A very strong faradic current passed through the metatarsus is substituted for the galvanic. Time and electrodes same as above. Primary current used.

August 8th.—But little swelling remains. Moves the foot without pain. Treatment continued.

August 13th.—Swelling nearly gone. Walks upon the foot without pain.

August 19th.—Except a little stiffness upon locomotion, all trace of inflammation has disappeared. Faradism continued.

September 1st.—All symptoms absent except slight stiffness at the metatarso-phalangal joint. Treatment continued.

September 8th.—Discharged to duty.

Case IV.—Gonorrhœal rheumatism of left foot; instep hot, tender, and tensely swollen. Duration seventeen days. No sleep at night on account of pain.

July 29th.—With an electrode, 1.77 sq. in., on each side of the instep, passed a galvanic current of three milliampères for five minutes. Lead-water and laudanum lotion.

August 1st.—Redness gone, pain abated, but swelling remains. Primary faradic current substituted, as strong as the patient can bear, ten minutes daily.

August 8th.—Pain and swelling abating steadily. Patient expresses much relief from the treatment.

August 16th.—No pain and but little swelling remain. Tenderness and swelling about the right inner malleolus, which is faradized as above.

September 1st.—Except a little soreness during locomotion, the left foot is well. Right ankle swollen, but less painful.

September 7th.—Pain and swelling absent from both feet, but some stiffness is felt upon walking.

October 1st.—Goes about all day without pain or subsequent swelling, but the parts are still a little stiff.

October 22d.—Well. Discharged to duty.

Case V.—Rupture of anterior crucial ligament of the right knee-joint.

February 6th.—Joint much swollen, hard, and painful upon standing.

June 30th.—A strong faradic current from the primary coil is passed through the joint for ten minutes; electrodes, 1.77 sq. in.

July 3d.—Joint less painful and swelling reduced.

July 8th.—Swelling nearly gone; pain felt only upon standing.

July 12th.—Same. Galvanism substituted, three milliampères for five minutes; electrodes, 1.77 sq. in., each side of joint.

July 20th.—No swelling remains. No further improvement was effected by electrical treatment of this case.

Case VI.—Female, nine years of age. Subarticular ostitis of right knee, neurotic (?). Duration five years. Joint much enlarged, with effacement of anatomical outlines, swelling most marked over inner side, which is the site also of tenderness. Skin somewhat red and marked by enlarged veins. The child passes a part of each night crying with pain. Partial anchylosis from muscular spasm.

August 5th.—With electrode, 1.77 sq. in., applied the anode labile over the joint, using a galvanic current of one-half milliampère for five minutes. Daily treatment.

August 12th.—No pain in the joint since the first treatment. Swelling appreciably diminished.

August 19th.—Swelling reduced one-half. No recurrence of pain. Joint less tender.

August 26th.—But little swelling remains, except over inner side of joint. Outline of patella easily made out. Cutaneous veins smaller.

September 10th.—No cutaneous veins appear. Swelling upon inner side of joint nearly gone. No tenderness.

October 1st.—Injunction of absolute rest violated. Return of swelling, with slight tenderness, but no pain. Cutaneous veins reappeared.

October 10th.—*In statu quo* September 10th.

October 20th.—Same. Patient still under treatment.

Lymphadenitis. Case I.—Indolent bubo of the right groin, of two months' duration and size of a small hen's egg. Consistence very hard. No history of chancre.

With the cathode, electrode 1.77 sq. in., on the bubo, a galvanic current of three milliampères was passed daily for five minutes. At the end of three weeks the patient was discharged to duty without a trace of the bubo remaining.

Case II.—Bubo in left Scarpa's triangle, consisting of several glands, from the size of a cherry to that of an almond, embedded in an inflammatory deposit. No explanatory history except a gonorrhœa present. Duration seventeen days; consistence of glands rather soft.

January 27th.—Galvanization of bubo, two milliampères for five minutes. cathode on enlarged glands, electrode 1.77 sq. in. Daily treatment.

January 31st.—Bubo subsiding rapidly.

February 4th. Bubo nearly absorbed.

February 11th.—Bubo has disappeared.

Case III. Monoganglionic bubo in right groin of the size of a small hen's egg; tender and somewhat soft, but without positive evidence of suppuration. Duration three weeks.

August 6th.—Applied the anode, electrode 1.77 sq. in., to the gland, and passed a galvanic current of two milliampères for five minutes. Daily treatment.

August 9th. Bubo somewhat red and more tender, as if it might suppurate, but a little smaller. Treatment continued, together with calomel vapor bath for constitutional syphilis, just manifest.

August 12th.—Signs of suppuration, but swelling abated about one-half. Galvanism suspended, mercury continued.

August 17th.—Redness, tenderness, and swelling diminished. Mercury continued.

August 26th.—All signs of suppuration have disappeared. Bubo considerably smaller.

August 31st.—Gland has returned to normal size.

Case IV.—Bubo in left groin, all the glands with inflammatory deposit forming a tumor as large as a hen's egg. Consistence doughy, with one small point of tenderness. Duration four weeks. No history of recent venereal sore.

September 24th.—Galvanization of bubo, cathode, electrode 1.77 sq. in., on the swelling, two milliampères for five minutes daily.

October 1st.—Glandular swelling diminished about one-half, the glands being now easily counted.

October 9th. Continued abatement of swelling.

October 13th.—Bubo reduced to three almond-shaped glands without intervening inflammatory deposit.

October 16th.—Two glands remain.

October 19th.—Two glands in right groin have become slightly enlarged. Patient complains of suspicious nocturnal headache. Galvanization continued, with the addition of Hydrarg. iodid. virid., gr. $\frac{1}{6}$ t.i.d.

October 23d.—Headache gone. Glandular swelling abating.

October 27th.—Glands in each groin about the size of cherries. Still under treatment.

CASE V.—October 12th.—Egg-shaped bubo in right groin, hard, except at one point, which is suppurating. Two olive-shaped glands in left groin. Glands began to swell about three weeks ago, two days after venereal exposure. No history of a sore. General health impaired. To have tinct. ferri chlorid. internally, galvanism locally, cathode on right groin, anode on the left, one milliampere for three minutes daily. Aspirated the suppurating point and injected solution of mercuric chloride (1 to 3,000) into the cavity.

October 16th.—Swelling in both groins diminished about one-fifth. Treatment continued.

October 20th.—Swelling reduced one-half in right groin, one-fourth in the left.

October 23d.—Suppuration has ceased. Right bubo about the size of a pigeon's egg, the left but little changed.

October 28th.—Right bubo almond-sized, the glands in the left groin are cherry-shaped. Still under treatment.

OPACITY OF THE CORNEA.—The treatment and progress of these cases were so nearly uniform that a brief abstract of each will suffice for the present purpose, which is to show that in the galvanic current there is a prospect of restoration of useful vision to many eyes hitherto regarded as hopelessly blind.

CASE I.—Macula, three by six millimetres in dimensions, over the right pupil, and a smaller nebula similarly situated upon the left cornea, both interstitial apparently. Duration two years. Treatment begun February 21, 1888, with a galvanic current of two milliampères for ten minutes, cathode on the closed eyelid, anode in the palm of the hand. At the end of a week the macula had become smaller and thinner, and the nebula not readily visible without oblique illumination. One week later the macula had become nebular, the nebula less changed, but both eyes showed conjunctival injection, and were painful; the treatment was therefore suspended for two weeks and then resumed, but with the poles changed, the anode being on the eye. The duration of the sitting also was shortened to three minutes. No further irritation was manifested. At the expiration of two months, the opacity of the right cornea could be seen only upon close scrutiny by direct light, that of the left only upon oblique illumination. Two months later the original macula had become two filmy fragments, while the nebula was scarcely visible with oblique illumination. Shortly after this the patient ceased to return.

CASE II.—Interstitial macula covering pupillary area of each cornea, due to recent trachoma of seven years' duration. Vision greatly impaired, patient barely able to find her way. Treatment begun March 1st with three milliampères for ten minutes, cathode on the closed eyelid, anode in the hand. Application made every other day without evidence of irritation.

June 3d.—Present condition: R. E., several very faintly seen scattered fragments of the opacity; vision satisfactory; L. E., cornea clear, except upon oblique illumination, which shows a small nebular spot; vision excellent. Patient seen no more.

CASE III.—Interstitial macula, two by five mm. over left pupil, the remains of a recent severe catarrhal ophthalmia with strumous diathesis. Vision greatly disabled. Treatment begun February 28th, with cathode on the closed lid, anode in the hand, three milliampères for ten minutes on alternate days.

March 12th.—Macula one half original size. Reads print easily.

April 1st.—Improvement progressive but less rapid. Daily treatment, two milliampères three minutes.

May 1st.—Macula very thin, one by two mm. in size.

July 1st.—No material change. Patient's visits very irregular.

September 1st.—Macula seen only upon close inspection. Patient departed for the country.

October 1st.—Macula unseen by anyone ignorant of its presence. Treatment resumed.

October 17th.—A tiny nebular spot remains. Patient departed for the United States.

CASE IV.—Dense leucoma below right pupil, four mm. in diameter. Duration fifty-eight years. Irregular treatment as above for two months effected a reduction to three millimetres, but patient ceased attendance.

CASE V.—Millet-seed leucoma below right pupil. Duration twenty-four years. Regular treatment as above for thirty days made no appreciable change.

CASE VI.—Interstitial macula of small size over each pupil. Duration two years. Treatment, one pole upon each eyelid, three milliampères for three minutes, daily. At the end of three months the opacities are now tiny nebulæ. Still under treatment.

CASE VII.—Nebula two by three mm. over left pupil, and occlusion of right pupil from presence of lymph. Duration one and a half year. Treatment, cathode on right, anode on left, eyelid, three milliampères for three minutes. After fifteen days the nebula was but a fraction of its original size, and is now, after four months, discovered only upon close inspection. The right pupil is slowly increasing in diameter, being now egg-shaped instead of linear, as at first. Patient still under treatment.

CASE VIII.—Leucoma, 4 mm., over right pupil, and connected by a bridge with a considerable deposit of lymph in the anterior chamber, which in turn is continuous with a similar deposit in the posterior chamber. Remains of ophthalmia one year ago. Resemblance to hypopion so strong that paracentesis of the cornea had been done twice before patient came for treatment. Treatment begun June 28th, with cathode, three milliampères three minutes, anode on the neck, daily.

August 1st.—Leucoma thinner; deposit in anterior chamber less dense.

September 1st.—Leucoma has become macular; bridge nearly gone. Deposit in the anterior chamber broken up and wholly gone in places. No appreciable change in posterior chamber.

October 1st.—Leucoma nebular; bridge wholly gone; iris merely dotted with the deposit in the anterior chamber. Deposit in anterior chamber appears smaller and less milky.

October 28th.—Steady improvement. Patient still under treatment.

CASE IX.—Interstitial leucoma, 5 mm. in diameter; dense grayish-white over right pupil. Cornea slightly conical. Duration eleven years. First treatment June 15th, cathode on closed eyelid, anode on the neck, three milliampères three minutes. Present condition, October 28th: Size of leucoma but little reduced; its opaqueness, however, is so far diminished that the iris can be seen dimly through it. Its complete disappearance appears to be only a matter of time and persistence with the treatment.

CASE X.—Leucoma and conical cornea of both eyes, permitting only qualitative perception of light, the whole of each cornea around the leucoma being clouded. Treatment begun March 4th; two milliampères for ten minutes; cathode on the closed eyelids.

March 10th.—Corneæ clearing. Patient comes alone.

March 12th.—Corneæ quite clear, except at the site of the leucomata. These are smaller, and the conical condition is diminished.

May 1st.—Leucomata have become macular, and the conical condition has quite disappeared.

June 1st.—Opacities are very thin and but a fraction of the original size. Patient failed to return.

In addition to the above, two cases each of incipient cataract and of deafness due to dry middle-ear catarrh, have been treated by galvanism with gratifying results.

THE CINCINNATI POLYCLINIC is the latest addition to the post-graduate schools of the country. It was organized on October 31st, and the trustees are about to purchase premises for the school, which will be ready for students about January 1, 1889. The dean of the faculty is Dr. Charles A. L. Reed.

CONVICTIONS REGARDING THE NOSTRILS IN RESPIRATION.

By WILLIAM A. DAYTON, M.D.,

INSTRUCTOR IN OTOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, NEW YORK.

THE intent of this article is a plea for the universal consideration of the nose as the beginning of the respiratory apparatus.

The arbitrary division of the respiratory apparatus into the "upper" and "lower" air-passages is the dictum of anatomists and physiologists; and this opinion is borne away by every alumnus of a medical school.

In "Gray's Anatomy," page 769, the chapter on "Voice and Respiration" begins thus: "The larynx is the organ of the voice, placed at the upper part of the air-passages."

On page 273 of Dalton's "Physiology" we read: "The respiratory apparatus in man commences with the larynx, which communicates with the pharynx at the upper part of the neck."

Again, "specialism" has, in the past, done much to divorce the "upper" from the "lower" air-passages, although recent writers on pulmonary diseases have, apparently, just stopped short of differing from the authorities on anatomy and physiology. In other words, the "professor" of thoracic diseases does not, as a rule, treat the naso-pharynx, and *vice versa*.

Dr. Loomis' lectures are introduced thus: "We are about to commence the study of the respiratory organs, and, most naturally, diseases of the larynx will first engage our attention." Strangely enough, the great Mackenzie, in Reynolds's "System of Medicine," opens the consideration of diseases of the respiratory system with the larynx.

All writers conform to the established custom of describing the nose as the organ of olfaction; and, in a stereotyped manner, accord it the credit of being a catch-all for atmospheric impurities, a vague auxiliary in the respiratory act, and the home of prolific catarrh.

Sustained by such statements, many celebrated instructors in vocalism, elocution, athletics, and in the use of wind-instruments teach, regardless of the dangers to which this fallacy surely leads, that the nose is incapable of meeting the demands of these occupations.

Yet more, these premises, once fixed in the mind of the practitioner, are frequently the occasion of unfortunate neglect. What greater obstacle to the recovery of inflamed lower air-passages can be conceived than superinduced mouth-breathing? And, pray, what author on the practice of medicine devotes a single line to the subject. No; the nostril and its diseases belong to the specialist.

There is no more reason for regarding the nose as a mere auxiliary to the lungs than there is in trying to believe that the external auditory canal is an auxiliary to the labyrinth. Though there are three channels by which sound-waves reach the labyrinth and three channels by which nutriment can reach the circulation, we have no doubt as to the normal channel. So while the mouth, with its various important organs, affords an easy access of air to the lungs, yet the nostrils can, the writer believes, be proved to be the normal channel for all inspiratory purposes.

The earliest history as to respiration occurs in the account of the creation: "And the Lord God formed man of the dust of the ground, and breathed into his nostrils the breath of life; and man became a living soul" (Gen. ii. 7). The Hebrew "Aph" being the singular for nose, "Appai" is used, a so-called dual, meaning the two nostrils. This is significant. More than one thousand years later, we find the Greek philosopher Aristotle at work on the subject of respiration (see "Respir.," chaps. iii. to vi.). The details as stated by him, though somewhat lurid, are so minute as to lead Agassiz to repeatedly say that not only had Aristotle anticipated many points in natural history which are regarded as modern discoveries, but he had reported facts of observation which could not be translated until new observations explained his meaning. The influence of respiration, he states, not only produces heat but gives life, since ceasing to breath produces death; while he manifestly indicates that in breathing through the nose there is an action of air (nitrogen?) on the sensorium at the base of the brain which promotes in some way the intelligence of the higher animals, and is especially promotive in man of energetic and clear mental action. Aristotle did not, of course, know the properties of the air, as made up of oxygen and nitrogen; the action of the former of which is now known to produce heat, while the latter, in plants, has been proved to be the direct source of life. The question that occurs to me is this: Was nitrogen, which constitutes four-fifths of the atmosphere everywhere, simply designed by the Creator as a diluent of oxygen?

The more I consider the peculiar structure of the nasal chambers, the spongy nature of the thinly covered turbinated bones, the large expanse of actual surface, guarded by mucous membrane so delicately constructed as to afford but slight protection to the extensive circulation, and varying in cell-formation at different points, the more I am convinced of their office in appropriating nitrogen from inspired air in the same manner as oxygen is appropriated by the lungs.

The idiotic facial expression observed in mouth-breathers is not due to the fact that the mouth is open so much as it is due to coexistent partial or complete deafness, to eyes as dull and expressionless as a fish's, and to the lack of mental vivacity; and those of us who have seen cured mouth-breathers will recall the total change, not only in the countenance but in the improved mental manifestations of such patients.

Dr. Roosa ("Diseases of the Ear," p. 203) refers to an article by Koppe in which the latter relates the history of two cases wherein treatment of the nose, throat, and ears restored the patients to sound mental condition.

Perhaps the most convincing argument for constant nose-breathing was written by Dr. Cassels, who chose the somewhat startling subject, "Shut your Mouth and Save your Life" (Reprint. Edinburgh: Oliver & Boyd. 1877.) Dr. Cassels quotes Mr. George Catlin, distinguished for his investigations among the American Indians, thus: "If I were to endeavor to bequeath to posterity the most important motto which human knowledge can convey, it should be in three words, 'Shut your mouth.'"

An interesting article on "Hatters' Consumption," by my friend Dr. J. W. Stickler (*New York Medical Journal*, May 29, 1886), well illustrates a point I desire to bring out. He concludes his valuable investigation as follows: 1. That pulmonary phthisis is the most common and fatal disease among hatters. 2. That this particular type of phthisis is due to a mechanical irritation of the lungs by the fur and dust which pervade the air of the "finishing" and "pouncing" room. 3. That the inhalation of fine fur hastens the progress of inherited or acquired pulmonary consumption. 4. That removal of the exciting cause is the only rational means of preventing or interrupting the disease.

In a letter dated July 6, 1886, Dr. Stickler sent the following notes, replying to inquiries in the line of my own observations, as to the existence of naso-pharyngeal diseases among the hat-makers.

"They (the hat-makers) inhale large quantities of the fine fur which pervades the air of the rooms; this fine fur lodges upon the mucous membrane of the nose and vault of the pharynx. In many cases the membrane becomes sufficiently thickened to interfere, perceptibly, with easy respiration. In such cases the membrane lining the nasal cavities is the seat of the greatest structural changes; it will not only show congestion and thickening but, very often, ulcerations which are sometimes superficial, sometimes quite deep. There is one more point, with reference to the character of respiration as practised by the hatters, they perform respiration in a very imperfect manner; *i.e.*. it is shallow, causing an expansion of that portion of the lungs at just about the first division of the bronchi upon either side. I am now speaking of respiration as performed in the shops while the men are at work. I have been told by hatters that they have blown black dust from their nostrils and hawked it from their throats, two and three weeks after leaving the hatshops."

These statements point unmistakably to the adoption of abnormal respiration, with two causes upon which its continuance is dependent, viz.: 1, Nasal obstruction; 2, habit—the former demanding surgical interference; the latter, proper breathing exercises, etc., each of which will be considered farther on.

This serves to indicate the danger to which upholsterers, bakers, stone-cutters, tailors, seamstresses, tobacco-workers, barbers, vocalists, athletes, performers on wind instruments, *et al.* are subjected; and my own investigations among those who are for any considerable period of time thus employed show: 1, That they usually have marked swelling or true hypertrophic changes in the upper air-tract, with ulceration as an occasional complication; 2, that they acquire an accompanying progressive middle-ear catarrh; and, 3, that mouth-breathing becomes inevitable.

The only objection to Dr. Stickler's able article is the title. What he has chosen to call "Hatters' Consumption" is but a synonym for the disease induced by an inorganic matter inhaled; and I am opposed to the further taxing of our already overstocked nosology.

We are frequently asked the question: Does nasal catarrh result in consumption? My answer to patients is always in the affirmative; and I tell them something like this: When the nostrils are at all obstructed respiration is carried on (abnormally), for the most part, through the mouth, especially during sleep, exercise, and in the use of the voice. Impurities are inhaled which collect on the mucous lining of the bronchial tubes and, ultimately, cause ulceration of the same.

I do not believe dust can reach the bronchus by way of the nose, nor that solid foreign matter of any description ever extends to the true pulmonary tissue. I believe that in all cases where the history of tuberculosis is not obtained the lesion causing cough, night-sweats, fever, emaciation, and hemorrhage will be found in the trachea or in the ramifications of the bronchial tube. Hemorrhage, in these cases, is nature's own admirable cure; for in this way alone can the deposit of foreign matter be removed, and in the treatment of such patients the fact should never be forgotten.

The structure and position of the nasal chambers are such as to meet the very purposes for which they were designed: 1. The structure of these passages provides for the tempering of inspired air; for the exclusion from the lower air-tract of irritants as well as infectious and contagious poisons; for the perception, to the best advantage, of odors; and for the maintenance of the necessary moisture for *unconscious* respiration. I use the word in italics, because consciousness of this function implies more or less disturbance. Yet more, the arrangement of the nasal chambers is such as to make provision for the lodgement of extraneous substance until nature, or instinct, or art removes them.

2. The position of the nostrils is significant. They are the portals to the lungs' highway. This is shown (1) by the continuity of the mucous lining; (2) by the physiological impossibility of breathing through the nose and performing, at the same time, the act of deglutition; (3) by the more direct anatomical plane, whereby (normally) air finds readier access to the lungs; (4) by the distribution of the pneumogastric nerve. Aside from this, the air-pressure in the tympanic cavities is dependent upon a normal condition of the beginning of the respiratory tract.

The child who cries violently becomes hoarse because the natural method of respiration is reversed; so the orator's voice becomes husky during excited bursts of eloquence or rage; the vocalist pauses to "clear the throat" after the execution of prolonged musical passages; the athlete "loses his wind" when pressed the hardest in strife, only to "get it back again" after studied nose-breathing.

Leaving this, perhaps unnecessary, digression, let us look at the practical issues.

For more than three years past this subject has been my chief thought. My interest in it has led to inquiries which plainly demonstrate a prevailing error, founded on statements of medical authors and which remain to be corrected. A large number of reputed vocal instructors, impressed with the idea that "the respiratory apparatus begins with the larynx," calmly advise their pupils "to breathe through the mouth or nostrils, according to the demands of their performance;" or, as one of them expressed it, "whichever comes the easiest."

A broken-down cornet-player, at forty, told me he had been taught by a foreign celebrity "to take in his wind by the mouth."

One of the noted runners of the day boasted that he "always runs with his mouth open." I shall watch the young man with interest. It is easy to foresee his destiny. More than a year ago I made the acquaintance of Professor Max Bendheim, of the Grand Conservatory of Music. Professor Bendheim, who is a good observer, had for some time been looking askance at the "breathing methods" as taught by the vast army of aspirants for fame in musical circles. He wondered at the disparity existing between the "methods" of several leading instructors in vocalism. That one man taught his pupils to retract the abdomen as a prerequisite to perfect inspiration, and that another taught thoracic gymnastics, with the mouth kept wide open, seemed to him mere jugglery of a trade. He had made himself familiar with all the arts and devices of his craft, and, though successful as the best of his rivals, his efforts were frequently disappointing. He came to the writer for an explanation regarding the improvement in the voices of several pupils who had been under his care.

These particular pupils, of both sexes, had been under instruction for a long time and all had excellent vocal "gifts." The general subjective symptoms were irritation in the larynx, dry throat, and difficulty in singing sustained notes. The general objective symptoms were collapsed nostrils, mouth-breathing, pharyngitis, and hyperæmia of the larynx.

The treatment consisted: 1. In suspending vocal instruction. 2. In dilating the nostrils with graduated cotton-plugs, medicated as occasion required. 3. Massage applied to the nasal wings. 4. Breathing exercises carried on exclusively through the nose, allowing about three seconds for inspirations and from ten to twenty seconds for expirations. One of these cases required the removal of hypertrophic tissue from the distal end of the inferior turbinated bones; in one other case the tonsils needed reduction. As nasal inspiration became easier the pupils were allowed to renew their vocal instruction, but they were permitted to sing only simple scales; and their studies were not advanced until their increasing dexterity in unvaried nasal inspiration became apparent.

Professor Bendheim agrees with the writer in believing that the larynx is not the beginning of the respiratory apparatus, except on artificial anatomical grounds. In rapid musical passages, where the singer has scarcely time to close the lips for an inspiratory act, the professor teaches a method whereby the base of the tongue is deftly raised against the soft palate and the inspiration is still taken through the nostrils.

During the past year I have enjoyed the honor of a most interesting correspondence with Dr. Feldbausch, of Wiesbaden, who has for a long time taken a lively interest in treating the "lower air-passages" by vapor-inhalations. He has presented in Europe a most unique device which deserves more than a mere passing notice. His "inspirator," as he calls it, consists of two flattened metallic tubes, each having a double roll of blotting-paper, to be saturated with any desired medication for inhalation. These tubes, made in three sizes, are introduced into the nostrils and kept *in situ* for any discretionary length of time. Dr. Feldbausch's claims for their efficiency are not at all unreasonable, and he believes that their extended use will prove all his premises. I have employed already over thirty of these "inhalers," and can commend their utility highly. The result of the doctor's investigations point clearly to the doctrine of the "beginning of the respiratory apparatus" herein set forth.

It is a self-evident fact that children, for instance, who are mouth-breathers, become the ready victims of the acute infectious diseases, and that those who have normal "upper air-passages" are comparatively exempt. Does this not explain why the lesion in so-called cases of "diphtheria" appears, as it always does (when the lining of the fauces is not rendered too insensible by hyperplasia, etc.), on the tonsils or the back wall of the pharynx? This question I can but consider in the affirmative.

In that supposed distinctive disease, "true croup," the tonsils and the lining of the fauces are usually the seat of hypertrophic changes which render those surfaces less susceptible to the production of pseudo-membranous deposit; hence the readiness with which the larynx and trachea take on the characteristic exudation and symptoms.

The necessity for free nasal respiration in health becomes an imperative demand in all conditions of ill-health. Especially is this true where we deal with the uncertain problems of bronchial and pulmonary inflammation. Imagine, if you can, a greater obstacle to the subsidence of inflammatory action in and below the larynx than the constant evaporation of moisture and the inhalation of a bedroom atmosphere, occasioned by mouth-breathing. Yet how often do practitioners think of this as an element in the nice management of cases like scarlatina, measles, whooping-cough, and the fevers in general, in all of which diseases the drainage and the ventilation of the nasal passages are likely to be bad?

This point is not touched upon by any work on "Practice" with which I am familiar; and I believe that, when this subject receives general consideration, we shall hear less frequently of laryngeal and pulmonary disease as the sequel of eruptive and other fevers.

In those rare and painful cases of faucial and laryngeal sloughing due to cancer, syphilis, and other causes, mouth-breathing is usually pronounced; yet in the reports concerning such patients as General Grant and the Crown Prince we read little or nothing as to this contributing cause of distress and *local irritation*.

Incident to the growing popularity of post-graduate instruction and the ever-increasing competition for a "living" in these times of medical oversufficiency, diseases of the nose, throat, and ear are treated extensively by the general practitioner, for whose especial benefit the following is written. In view of the prevalence of these affections, those gentlemen who are most familiar with the subject agree in pronouncing a normal nose, ear, and throat to be almost objects of curiosity. Hence the greater importance of recognizing the indications for interference and the most appropriate means of securing the best results.[1]

In concluding this necessarily disjointed article, let us remember that the physiology, the pathology, and even the anatomy, of these highly organized cavities (the nostrils) are still in the infancy of our comprehension. The history of the treatment of naso-pharyngeal disease, during the past eight or ten years, reads like a fairy-tale of science, and makes us wish for the "long results of time." Since the destructive plan of treatment has been made bearable by the new anæsthetic, galvano-cautery has become the rage of to-day; and it is to be feared that this novelty is playing sad havoc with an organ the physiology of which is but meagrely comprehended. By extended study of this subject we may hope to explain away many scant physiological observations as to respiration; more than this, in the possession of a complete and generally appreciated knowledge of these organs, we will do our fellow-creatures better service by preventing or limiting progressive nasal disease than by blindly following out the stereotyped system of "cure."

The importance of recognizing the nostrils as the beginning of the respiratory tract is thus imperfectly presented. The writer believes that the excessive devotion to authority is just as great a stumbling-block in the way of progress as too littte respect for it. Hence the hope is expressed that all future editions of text-books will accord the nose, with all its connections, both in health and disease, the place it should hold; because the impartial observer of its construction and offices cannot fail of assenting to the irresistible evidences of harmony and design.

13 West Twenty-sixth Street.

URINARY EXAMINATION IN LOCALIZING GONORRHŒA.

By H. GOLDENBERG, M.D.,

NEW YORK.

It is only within this decennium that the treatment of urinary diseases, especially gonorrhœa, a disease so widespread and so long known, has been established upon a firm scientific basis.

This was made possible through the improvements in diagnostic methods, and because it was seen that a proper treatment could only be pursued by an accurate determination of the exact localization of the affection.

The endoscope is the most important aid for this purpose. Although this instrument has been vastly improved within recent years, yet it will be a long time before it comes into general use. The busy practitioner has neither sufficient time in his office nor the requisite practice in the use of the instrument; a diagnostic method is necessary which will consume the least possible time for localizing the disease.

We have such a resource in the test known as Sir Henry Thompson's, consisting in the collection of the urine (voided once) in two portions.

As we are unable to find any mention of this important test in any American treatise, and as we are well assured of the practical worth of the same, we shall endeavor, in the following pages, to set forth its value as briefly as possible.

This test is based upon the separation of the canal in two portions, namely, the anterior and posterior urethra, separated from each other by the muscularis compressor partis membranaceæ ("cut-off muscle"). Through our experiments, the results of which we have given in an article in the *New York Medical Press*, June, 1888, we are able to confirm the fact that the separation is not arbitrary, but natural and practically important. Moreover, we state, in opposition to certain adherents of the Vienna school, who claim a division of the urethra, that the boundary line between the posterior part of the latter and the bladder is given in the muscularis sphincter internus, of which the resistance is less than that of the muscular compressor, but nevertheless adequate to prevent the penetration of a not excessive quantity of fluid into the bladder.

According to this division, then, of the urethra into an anterior and posterior part, we differentiate a urethritis anterior and posterior depending on whether the affection extends to the bulb of the urethra or the pars membranacea and prostatica.

Guyon has positively determined, and practical experience daily confirms this view, that the urethritis can be wholly limited to the anterior part without affecting the posterior parts, just as much so as an affection of the cervix may be limited to that without involving the rest of the uterus.

---

[1] This will be considered in a separate paper.

Before entering upon the discussion of Thompson's test we will consider what change the urine undergoes in gonorrhœa. It differs in different stages of the urethritis, depending upon the nature and amount of the secretion, no matter originating in the anterior or posterior urethra. In the acute stage of gonorrhœa we find a cloudiness of the urine, depending upon the amount of the discharge, composed of pus and mucus, which settles on the bottom of the beaker in two layers, the layer of the pus being below that of the mucus. This cloudiness is not to be confounded with that due to phosphaturia, which is frequently found in urethral affections.

In a subacute and chronic course of the disease the layer of pus diminishes, and in place of it we find peculiar formations, the so-called "Tripperfaeden" (gonorrheic filaments). Macroscopically they are seen as shreds or flakes, either short and thick, or long and thin. Microscopically they are found to be composed of pus-cells and epithelium, embedded in mucus. They are sometimes falsely regarded as a sign of beginning recovery, or, as happened in a case that came under my observation, as originating from stomach trouble. On the contrary, they always accompany, or rather are caused by, the slight morning discharge, indicating that the process—no matter how old—has not yet healed.

The Thompson test is performed by causing the patient to urinate in two beakers, each containing about two ounces. Practically there is but a single alternative: either the urine in the first glass is cloudy, with or without the above-mentioned filaments, according as the process is acute or chronic; the urine in the second glass being clear; or the urine in both glasses exhibits the preceding lterations.

What conclusions may be drawn from the foregoing? The cloudiness or filaments in the first glass is generally held to show that the forward portion of the urethra is alone affected, the posterior urethra and bladder being normal. The urine in both glasses being cloudy, there is, with or without a urethritis anterior, a urethritis posterior or cystitis; in the case of urethritis posterior the first glass being cloudiest, in a case of cystitis the two glasses equally cloudy, or the second one the cloudier.

Are we entitled to draw the foregoing conclusions, and upon what line of argument may they be based?

Our opinion is that the first query should be replied to in the negative. For if the urine in the first glass is cloudy or has filaments, the second one being normal, we can only conclude that there is no cystitis; since in a case of cystitis the entire urine would show alteration. The test as laid down gives no hint as to whether the anterior or posterior urethra, or both, are the seat of gonorrhœa, for the first urine, in its passage through the urethra, washes out the back no less than the front part of the canal. This fact is, of course, not unknown to the authors who advocate the Thompson test, but they maintain that the discharge in a case of urethritis posterior enters the bladder, having no room in the urethra posterior itself, and being prevented from running outward by the cut-off muscle already mentioned. This being the case, they conclude that in a case of urethritis posterior, the second urine would be also changed. We are convinced, in opposition to this opinion, that several cubic centimetres, a not inconsiderable quantity of secretion, can remain in the posterior urethra without entering the bladder, and therefore the urine in the bladder is changed only if the discharge from the urethritis posterior is considerable. But we know that in cases of gleet there is very often but a slight discharge; so slight, in fact, that if the patient passes a large amount of urine (which is the more likely to occur from the diuretic action of the internal remedies most in vogue), the first urine cleanses the whole of the canal. Suppose that in accordance with the conclusions from the current teaching we have the patient urinate for the examination early in the morning, as recommended, on the ground that during the night the discharge has accumulated in the posterior urethra and may have had the opportunity to run back into the bladder. We admit that this may be plausible in certain cases, but there are many instances where patients are obliged to urinate during the night, and other cases where the discharge is so little that even if no urine is voided at night the discharge will not leave the posterior urethra: hence the test has no absolute value.

Having paid special attention to this subject I found the examination of the urine to be of great value, if the anterior part of the urethra was washed out before urination. I will explain this method and its value as briefly as possible:

A patient suffers from a gonorrhœa. If he has a quite recent urethral discharge, the first point of the treatment will be to do locally as little as possible. As a rule, the process is confined to the urethra anterior for the first two or three weeks; too early examination of the diseased urethra will do more harm than good. In the beginning of the inflammatory stage there is only a hygienic and dietetic treatment indicated, no difference what part of the urethra is affected.

As soon as the acute pain has passed, our duty will be to localize the disease by means of the examination of the urine. The best time will be in the morning, for reasons mentioned before.

The irrigation is accomplished by throwing a stream of hot water (110° to 120° F.) through a soft rubber catheter, put into the urethra as far as the bulbus, by means of a fountain-syringe. By this procedure, besides cleansing the urethra anterior for diagnostic purposes, we also gain a therapeutic aim. (Hot water retrojections, as recommended by Dr. Holbrook Curtis, of New York.) Applied carefully, this method can do no harm, the injected fluid cannot penetrate into the deep part of the urethra on account of the muscular compressor, and to render this closing still more complete the pressure in the perineum will be advisable.

The water used in the irrigation will reveal to us whether there is a secretion in the anterior urethra or not, and its nature.

Then we get the patient to pass his water into two beakers. It is certain that any clouding found in the beakers must emanate from the posterior urethra or bladder. If from the former the first urine will be cloudy; if the bladder is affected, both. If both are involved the cloudiness in the first beaker will be greater than that in the second, because to the sediment of cystitis will be added the gonorrheic filaments, etc. The test is of still greater value in subacute and chronic gonorrhœa, because the objective symptoms are less than in the acute, and the only symptom we find is very often only an alteration of the urine.

In conclusion, the advantage of this method is amply shown inasmuch as we are thus enabled to localize more accurately the affected portion of the urethra, whereas formerly in doubtful cases we could only differentiate the affection as located in the urethra in general or in the bladder.

107 East Fifty-ninth Street.

A Noble Fee.—Sergeant-Major Freyer, M.D., I.M.S., has received a fee of one lac of rupees (£10,000 sterling) from H. H. the Nawab of Rampur, as a token of esteem as well as an acknowledgment of his valuable services in the successful treatment of himself and General Azimuddin Khan, the popular head of the Administrative Agency of the State, who had suffered for nearly three months from a malignant rheumatic fever; his recovery has been the occasion of great rejoicing at Rampur. This is said to be the largest fee ever received by a medical practitioner in India, and probably has never been exceeded in any country.—*British Medical Journal*, October 6, 1888.

AN INTERESTING CASE OF STRANGULATION OF A PORTION OF THE ILEUM THROUGH AN OPENING IN THE MESO-RECTUM, PROBABLY OF A CONGENITAL NATURE.

By M. S. KAKELES, M.D.,

ATTENDING SURGEON, OUT-PATIENT DEPARTMENT, MOUNT SINAI HOSPITAL, NEW YORK.

In the present state of advanced scientific researches in surgery we have become bolder in our operations and undertake such as, ten or fifteen years ago would have been considered entirely hopeless. Especially is this the case in abdominal surgery. There is no doubt that many lives could have been saved were it not for the lamentable fact that surgeons were not yet well acquainted with the surgical treatment of the abdominal organs. They hesitated to perform laparotomy, fearing the almost certain peritonitis which they thought would necessarily follow such procedure. Only since they have become more enlightened in the methods for avoiding this dreaded consequence by strict antiseptic precautions, and become better acquainted with the details for performing operations in this region, have they overcome their antipathy to opening the abdominal cavity. We are not perfected to that degree as will warrant the indiscriminate use of the knife in all cases, but certain it is that an early laparotomy may save life in many cases.

We need but examine our post-mortem records for confirmation of this assertion. No case could better exemplify this than the following, which came under my observation on the evening of March 2, 1886:

I was asked to call on Mr. J. S——, a barber, who had been sick several days, and had been treated for obstinate constipation. When first seen the patient was perfectly conscious, had stercoraceous vomiting, rapid pulse, almost normal temperature, and face and body covered with a profuse perspiration. He told me he had been constipated for the six or seven days preceding, and that he had been taking various cathartics, which did not have the slightest effect. His abdomen was slightly distended and tympanitic. No tumefaction could be felt, and only slight pain in the left inguinal region could be elicited on percussion. A diagnosis of intestinal obstruction, either of internal hernia or volvulus, was made. Notwithstanding the collapsed condition, I gave large enemas of soapwater (the patient having been placed in the hand-and-knee position) without any satisfactory effect.

Opiates and stimulants were administered. The patient gradually sank, and died twenty-four hours after I first saw him, perfectly conscious to the last.

Post-mortem, twelve hours after death.—Body well nourished, moderately fat; chest large, well formed; abdomen slightly distended, considerable fat. Diaphragm on right side on a level with fourth rib; on left side, with fifth. Thorax: Lungs moderately collapsed; on incision œdematous and congested. Heart normal. Abdomen: Liver reached to free border of ribs. On lifting up the omentum, it was found slightly attached at its lower end by old adhesions. The small intestines were markedly distended. The transverse colon collapsed. On raising the distended intestine, a small coil, contracted and empty, was found lying against the spinal column. Below this a small loop was found deeply congested and strangulated, which seemed to have slipped through an opening in the meso-rectum. This loop was a continuation of the coil of ileum which was found contracted and empty. The strangulated portion of the gut was about a foot long, and was situated about six feet from the ileo-cæcal valve. The large intestine was empty and collapsed. The stomach and small intestine above the constriction contained a greenish fluid. Kidneys and bladder normal.

Whether this peculiar deformity was congenital, or the loop of ileum slipped through the opening in the meso-rectum and became gradually constricted during the time of the attack was not easily to be determined. The presumption is that it was a congenital malformation, and through an attack of constipation became constricted. There did not seem to be any indications of its being of a recent origin. The loop of intestine was easily withdrawn from the opening, which was round, and about the size of a silver quarter. The constricted gut had not yet become gangrenous, but was of a dark, deeply congested color. The ring pressing on the walls of the intestine interfered with the return circulation in this portion, and thus contributed to the strangulation. The patient gave no history of violent exercise, such as jumping or a fall, which possibly could have caused the propulsion of the intestine into the ring. He merely stated before his death that he was frequently constipated, and thought that this was only a bilious attack of more than an ordinary character.

This case is instructive in more than one way.

1st. As regards diagnosis. Intestinal obstruction there was, but could the character have been made out? Its locality in the small intestine was also diagnosed from the rapid setting in of feculent vomiting and tympanitis, besides the collapsed condition in the region of cæcum and colon. Had the constriction been in the large intestine the colon and cæcum would have been distended. Intussusception is rare in old persons, and besides patient gave hardly any evidence of pain and none of tumefaction. The rectum was perfectly clear, as evidenced by the copious injections of water. A careful examination of the pelvic and abdominal apertures, for external hernia, was made with negative results. The diagnosis of either internal hernia or twisting of the gut was therefore made by exclusion, judging from the sudden onset of the symptoms.

2d. Was it advisable to have recourse to operative interference? Medical treatment had been tried without any effect, and even though the direct cause could not have been ascertained, this would have been a proper case for operation, as the post-mortem afterward showed.

At the present time the surgeon is not confronted with the dangers following such operations as often as he was ten or fifteen years ago.

The obscurity in diagnosing the case as one of ileus, or obstruction from mechanical cause, should not deter the surgeon in the present state of antiseptic surgery from making an exploratory incision in the abdomen.

In the above case the patient had the best of chances had laparotomy been performed before he fell into a state of collapse. It required but the slightest effort to withdraw the congested loop from the constricting ring. The gut had not yet become gangrenous, but was merely in a state of deep congestion; it in all probability would have regained its vitality after prompt reduction.

Even though patients should succumb after a laparotomy, the surgeon feels that he has fulfilled a moral obligation and has given his patient the full benefits not only of his skill but also of the present advanced state of scientific surgery.

Treatment of Ascites by Faradization.—The treatment of ascites by faradization was recommended by Tripier in 1861, but Solfanelli, in 1866, was the first to report a favorable result from such treatment. The case was one of cirrhosis of the liver, and every means had been tried in vain to effect the removal of the fluid by increased diuresis. An increased excretion of urine was noted after the first application of electricity, and after four séances the ascites had entirely disappeared. As the causal hepatic condition remained unchanged, however, the fluid quickly reaccumulated. Dr. Muret has recently reported two cases of ascites, one following tubercular peritonitis and the other an enlarged spleen. In both cases a complete, though temporary, disappearance of the ascites was obtained by faradization.—*Der Fortschritt*, No. XX., 1888.

Clinical Department.

A PECULIAR SUBSTANCE FOUND IN THE HEART AND AORTA.

By BURT J. MAYCOCK, M.D.,

BUFFALO, N. Y.

Mrs. R——, aged eighty-two; no history of rheumatism, diphtheria, scarlet fever, or any severe strain. About two years ago she had an apoplectic attack, which, passing off, left no paralysis, but a great amount of general weakness from which she never recovered. At intervals since that time she has had similar attacks, always leaving her with headache, mostly on the left side, and more or less amnesia. When I saw her after an attack of this kind, about six months ago, she presented the following symptoms: Complete loss of memory of words, but her understanding was not much impaired. Tongue, when projected, inclined toward the left. On the left edge of the tongue near the tip was a purpuric spot about five centimetres in diameter. The heart's action was weak and irregular. Physical examination showed the heart to be in a condition of dilated hypertrophy. Over the mitral area, and carried around into the axilla, but not heard behind, was a short, high-pitched bruit, commencing just after the beginning of the first sound and terminating either with the sound or, usually, a little before. That is to say, it was a post-systolic mitral murmur, through which the normal first sound could be distinctly made out. The second sound over the pulmonary valves was not accentuated. Over the aortic area nothing abnormal was noticeable, except that the sounds were not perfectly clear and well defined. The lungs were somewhat œdematous. On November 5th she had an attack more severe than usual, followed by heart failure and death.

As I had never been able to satisfy myself as to the cause of the murmur, a post-mortem was obtained, and the following condition of things was found. The heart was much enlarged, weighing fourteen ounces. The left lung was greatly shrunken, and the bases of both lungs were in a condition of brown induration. The liver was somewhat contracted, dense, and on section presented a "nutmeg" appearance, and contained one or two small infarcts. The kidneys were enlarged and also contained infarctions, the left one in addition having three small cysts.

On opening the heart the ventricular walls were found to be thin and the cavity large. On the posterior wall of the ventricular cavity there were no columnæ carneæ, but the surface presented a ragged appearance, with what looked to be broken muscular fibres projecting from it. The mitral valves were perfectly competent. Attached to the infero-posterior portion of the cavity was a thin, tough, membranous substance about one-half inch in width at its point of attachment, then becoming narrower as it extended upward, floating freely in the cavity, passing in front of the mitral orifice and reaching to the aortic valves. Here it became very narrow and twisted as it passed through the centre of the aortic orifice, the attenuated neck offering no obstacle to the closure of the valves. Attached to this "neck," immediately above the valves and floating perfectly loose and free in the aorta, was a white, perfectly smooth and shining, fibrous, cylindrical body, about one and a half inch long and one-fourth of an inch in diameter. The brain was not examined.

All the symptoms found during life were now easily explained. The apoplectic attacks and the hemorrhagic infarctions were no doubt caused by small clots of blood (emboli) or, possibly, by pieces of the structure itself being washed away. The membranous mass in the left ventricle in the course of the blood-current caused the bruit, but the round smooth portion in the aorta gave no sign.

The question is, what was this substance? Was it a ruptured columna carnea? Or was it a clot which had become organized? Or was it a congenital condition? Whatever may have been the origin of the growth, the case is worth reporting if only to add emphasis to the fact that all endocardial murmurs do not necessarily imply valvular disease.

THE LOCAL TREATMENT OF DIPHTHERIA BY VLEMINCK'S SOLUTION OR SULPHURET OF CALCIUM.

By GEORGE E. HUBBARD, M.D.,

NEW YORK.

It would seem as though the time for discussion as to the constitutional or local inception of diphtheria had passed. The pathogenic bacteria of this disease have been discovered, and it is evident that it is their development and multiplication upon a mucous surface and extension to deeper parts and consequent blood-poisoning, or strangulation, which endangers the life of the patient.

The local inception appears to be so satisfactorily proven that the question at present is, What is the safest and most effective application for the destruction of the germs, or to arrest their development?

We know that good results have been obtained by the use of bichloride of mercury solution, peroxide of hydrogen, hyposulphite of soda, etc., but the one which I have to suggest, although not a new preparation, is, I believe, new in the treatment of diphtheria, and in my practice has given most satisfactory results. I refer to Vleminck's solution, or sulphuret of calcium, a preparation which has been used for years in the treatment of itch and certain skin diseases.

It occurred to me nearly two years ago that, if it is so effective in destroying the itch-mite, it would serve a good purpose in diphtheria, and I therefore tried it, at first carefully, with a camel's-hair brush, on my next case, to my great satisfaction. I now use the clear solution undiluted, by means of a spray, every half hour until the disease is under control, and then at longer intervals. In cases of very young children it may be best to add a little water to the solution at first until we are satisfied that it does not irritate the tender mucous membrane, but I have almost invariably used it pure, and have met with such marked success that I use no other local application.

In certain cases, every member of a family has been afflicted at about the same time, which would indicate that the diagnosis was correct.

It is not to be understood that this is all I do in the treatment of diphtheria, although in many cases I think this would suffice. I always make a practice of thoroughly fumigating the apartments with sulphur, and use such medicines as my judgment dictates. The principal thing to do is to destroy the disease-germs as early as possible.

The solution is prepared as follows:

Take, of lime, one part; sulphur, two parts; water, twenty parts. Slake the lime with some of the water, then add the remainder and the sulphur; boil to twelve parts and filter.

Under the use of this solution in spray, even sparingly applied, the diphtheritic patches undergo a change in a few hours. The temperature soon subsides, and a general improvement in the condition takes place almost from the first application. In some cases the patches disappear entirely in a day. If the false membrane has developed rapidly before the physician has seen the patient, under the influence of the spray it will be effectual even then in arresting systemic poisoning, and sooner or later the tough membrane will detach itself. Do not by any means allow the patient to swallow any portion of the false membrane. By gentle manipulation it can sometimes be removed without causing any irritation.

I have no doubt that the solution under consideration does much toward preventing constitutional infection as it is taken into the patient's stomach. Its stimulant, laxative, and somewhat diaphoretic and diuretic action are quite marked.

ABSCESS OF THE LEFT LOBE OF THE LIVER —EVACUATION BY INCISION INTO THE ABDOMINAL WALL—RECOVERY

By HAMILTON WILLIAMS, L.K.Q.C.P.I.,
BROOKLYN, N. Y.

THE patient, John D——, was seen by me for the first time on October 14th of this year. He was a native of Ireland, resident in this country for over forty years, had never been South, was fifty-four years of age, rather under the middle size, robust and hardy of aspect. He was never sick before, save an attack of pleurisy twenty-eight years ago, and was fairly abstemious in that he rarely drank spirits, although apt to indulge at times in ale. He was a carter by occupation, and up to a week or so previous to his sickness had lived in a one-story frame-house which had a privy in the yard. He complained of a hard lump in the abdomen, somewhat larger than the closed fist, occupying the lower half of the epigastric and the upper part of the umbilical region. Two-thirds of its bulk was to the left of the median line. There was but little bulging or protrusion. To the touch it was doughy, but of considerably more consistence, and non-nodular. Slight but deep-seated fluctuation was just appreciable on palpation over its centre. No discoloration of the skin, no infection of the superficial abdominal veins, no jaundice, no splenic enlargement; pulse, 78; temperature in axilla, 98° F.; no history of rigors. Painless under ordinary handling, the swelling, nevertheless, developed, under steady pressure, deep-seated, dull pain, non-lancinating. A considerable meteorism veiled most of the normal, and all of a possible abnormal hepatic dulness. There was no irregularity of the femorals at Poupart's ligament, and no pulsation in the tumor. According to the statement of the patient, his bowels had not moved for over nine weeks, and the swelling was noticed by him for the first time some two weeks after the stoppage of his motions. While the best working diagnosis appeared to be abscess of the left lobe, there was room for that of fecal impaction in the transverse colon—perhaps of the coexistence of both conditions. I advised an incision into the tumor to give vent to the pus externally, and forestall a fatal bursting into the cavity of the peritoneum. The patient's family failed to accede to the proposal, and I thereupon withdrew from the case. Three days subsequently I was asked to revisit the sufferer, and meet Dr. J. H. Ripley, of New York. By this time the swelling was much increased, and protruded as to its centre, but the continued absence of discoloration left it a matter of doubt whether the pus of itself would secure an exit within or without. The general characteristics of the tumor and of its surroundings remained. An exploring needle, plunged by Dr. Ripley into the swelling, well on either side, brought forth a quantity of not bad-smelling chocolate-colored pus. With his concurrence I then made a free incision of two and a half inches length into the most prominent portion, and we were treated to over two quarts of the pus described. The opening was protected with a wide covering of lint, wet indifferently with carbolized oil, or corrosive sublimate solution, outside which was a wider and larger layer of marine lint. The discharge, copious at first, gradually decreased, ceasing altogether with the final cicatrization of the incision in three weeks' time. Its characteristic color was retained to within a few days of its cessation. No hectic at any time. Brandy and quinine were rather generously administered at first, but the former was soon discontinued, and the latter reduced considerably. To meet any surviving hepatis inunction of the red iodide of mercury ointment over the liver, and a general sponging of the body with a solution of nitro-hydrochloric acid in water were resorted to. With the same object nitro-hydrochloric acid and taraxacum were exhibited, to be thrown aside later for a ferruginous tonic. The bowels were kept open by sufficient morning doses of Carlsbader salts. The patient is to-day in admirable health, and fully able to follow his former avocation. There are, in conclusion, some few points to notice of decided interest. A movement of the bowels following a dose of Carlsbader salts, administered on the third morning after the incision, brought away an enormous quantity of fæces mixed with pus and blood. The amount of the fæces would seem to indicate that it was one of the factors in the abdominal enlargement, which indeed did not altogether disappear until after this evacuation, whilst the pus and blood point to a perforation of the colon. It will be remembered that the patient stated that his bowels had been constipated for over nine weeks. This he invariably reiterated. One day, however, toward the close of my attendance, when I was thinking of writing up the case, I again put the question, adding: "You don't mean to say that all this time you never went once to the water-closet, if it was only to try and strain to bring on a motion?" The answer came quickly: "Oh! doctor, I used to go to the water-closet eighteen or nineteen times a day, but I never could pass anything. All that used to come away was a little blood and slime." Further questioning, which followed on this startling answer, developed the fact that he had passed unaided through an attack of dysentery, which numbered among its sequelæ the hepatic abscess I have just described. The only traces left of the attack over and above the cicatrix of the incision are found in wide adhesions to the abdominal wall evidenced on percussion

IMPERFORATE HYMEN.

DR. BLAKE BIGELOW, of Malone, N. Y., reports the following case of a young girl who was suffering great pain: "Two physicians had been called, but had discovered only a case of retention of urine. After several hours spent in attempting to introduce a catheter, they went away and I was sent for. I found the girl, who was fifteen years of age, in great pain, and in imminent danger of rupture of the bladder. The other doctors had told her that she was not a woman but an hermaphrodite. On separating the labia majora, I found a wall or septum in no way resembling a hymen, but strong and muscular in formation, and beginning at the lower portion of the fourchette, extending around the inner margin of the labia minora on both sides, up to where the clitoris should naturally have been. Every part of the cavity could be plainly seen. There was no appearance of the meatus urinarius, but at the upper juncture of the septum with the wall of the vagina there was a dimple-like opening much smaller than a small-sized pea. I took a No. 5 catheter, and using considerable force, passed it through this opening into the bladder and relieved the retention. The pain ceased at once; but there was a large movable tumor in the abdomen still. On palpation I found the septum yielded to pressure, with some sense of fluctuation, and that it was outwardly convex. I decided that the girl had been menstruating for several months, but as there was no outlet for the flow, the vagina and uterus had become filled with fluid. The latter was the size of a gravid uterus at the fifth month. I proved this diagnosis with a hypodermic syringe. On making an incision I took away three quarts of a brown, inky fluid. The uterus contracted to its normal size at once, and there was no further difficulty of any kind. The wall through which the incision was made was fully five-eighths of an inch in thickness. The vagina and uterus were normal, and the girl has since menstruated without difficulty."

THE CHICAGO POST-GRADUATE SCHOOL has recently been organized and incorporated, and will soon be ready for the reception of students.

Progress of Medical Science.

The Mortality of Abdominal Section.—At the recent meeting of the Royal Medical and Chirurgical Society (*The Lancet*), Mr. W. A. Meredith read a paper entitled, "Remarks on some Points Affecting the Mortality of Abdominal Section, with Tables of Cases," of which the following is an abstract. The purpose of the paper was to draw attention to certain points affecting the present death-rate after abdominal section, and with this view operations for ovarian growths were chosen as being to some extent representative of the entire subject under consideration. As a basis for the inquiry, the results of the author's own work in this connection, amounting to 126 operations, were examined with regard to the chief causes influencing the mortality, special reference being made to the ten deaths which occurred in the series of 104 completed ovariotomies. All the operations were performed with strict antiseptic precautions, including the use of the carbolized spray. He was now less inclined than formerly to look upon the latter as an absolute essential to the safeguards of antiseptic abdominal surgery, but he still considered it valuable as the most convenient and effectual means of antiseptic irrigation at our disposal when dealing with the peritoneal cavity. Both ovaries were removed in seventeen cases, two of which terminated fatally, but in neither instance was the result in any way attributable to the removal of the second ovary. Complete enucleation was performed in five cases, all successful, the resulting rent in the broad ligament being closed by means of a continuous silk suture. He advocated the use of the drainage-tube in all cases of ruptured or inflamed cysts, in any case where irritating or septic fluid had escaped into the peritoneum, in all operations complicated by serious injury to bowel or urinary bladder, in every instance where washing out had been resorted to, and in all cases of severe operation in middle-aged or elderly women. For washing out the peritoneum, where necessary, he advocated the use of plain, recently boiled water, cooled as required by the addition of a saturated solution of boric acid. Discussing the mortality, he was inclined to believe that in large series of cases the average death-rate would never be less than 5 or 6 per cent. Of the ten deaths in his series two were from septicæmia, one from intestinal obstruction, one from hemorrhage, one from dysenteric diarrhœa, two from chest complications, and three from exhaustion; three of these deaths were from preventable causes. Twelve successful operations for the removal of diseased uterine appendages were next reviewed. In seven patients, in whom both appendages were removed, complete arrest of menstruation followed. He had found that in cases of chronic ovarian mischief about 90 per cent. were the subjects of obstinate constipation, and in them tonic purgative treatment, by lessening pelvic congestion and preventing the formation of scybala, was followed by marked relief of symptoms. Included in a series of ten exploratory operations were two incomplete ovariotomies. Both patients had been tapped, and the death of one was directly due to the difficulties encountered in the attempt to separate universal adhesions which had resulted from this treatment. In conclusion, it was shown that the increased success of abdominal section for ovarian disease during the past ten years was chiefly attributable to the diminution in the number of deaths from septicæmia. For purposes of comparison he took three successive groups of operations, which represented three separate periods during the last twelve years, and gave their average death-rate from septicæmia alone. In 100 consecutive cases taken from Sir Spencer Wells's work, when the clamp was used and before the employment of antiseptics, the mortality was ten, or one to every ten patients. In 150 cases recorded by Mr. Thornton, in the sixty-fourth volume of the Medical and Chirurgical Transactions, which were treated antiseptically and with intra-peritoneal ligature of the pedicle, there were five deaths, or one to every thirty patients. In his own series of 104 cases there were two deaths, or one to every fifty-two patients. The chief factors which had contributed to this increased success, he thought, were as follows. (1) The general adoption of the intra-peritoneal treatment of the ovarian pedicle; (2) the application of the antiseptic system to abdominal surgery; (3) the gradual abandonment of the practice of tapping abdominal cysts; (4) the increase in our knowledge respecting the proper use and management of the drainage-tube; (5) the recent introduction of the plan of freely washing out the peritoneal cavity in cases complicated by the extravasation of blood or other fluid.

Case of Deficient Œsophagus.—Dr. Steele has recently observed a case of deficient œsophagus, and gives the following report of it in *The Lancet.* It concerned an infant twenty-four hours old, who, shortly after being given nourishment, a little of which was taken readily, became very livid, had difficulty in breathing, and then returned the food and appeared no worse. The gentleman in attendance introduced a sound, and found that it passed about five inches and encountered an impassable obstruction. He then asked Dr. Steele to see the child, and he repeated the sounding with the same conclusion. They diagnosed that there was either a membrane across the œsophagus, or that it ended in blind terminations; and he advised that through the night enemata of dessert-spoonfuls of peptonized milk should be given every two hours, and that by daylight the stomach should be opened and the œsophagus explored; if a membrane could be made out across a continuous canal, that it should be perforated in order to give a hope of life; and that, if we found any distance existed between the extremities, we could do no more; the parents, however, might feel that every possible endeavor had been made to save their child's life. This was agreed upon, and the father willingly acceded. On the following afternoon Dr. Steele was asked to perform the operation. The infant took chloroform well. He opened the abdomen above the umbilicus in the middle line, exposed the stomach, and stitched it at four points to the skin, having some difficulty to keep the liver from protruding. The stomach was then opened, which was perfectly healthy, and of course empty. A bougie was passed down the œsophagus as before, and another upwards from the stomach for a short distance; but they did not approach each other by what we judged to be an inch and a half. He then cut a gum-elastic catheter in half, and passed it from below, introduced up it a long slender steel probe, and pressed it upward as much as was justifiable, in case the lower part of the tube might be twisted or narrowed, and capable of being rendered pervious. All was of no avail, however; so the stomach wound was closed with sutures, also the abdominal wound, and we felt sure that the œsophagus was deficient for about an inch and a half. The infant slept for some time, and died twenty four hours afterward. The next afternoon they made an examination, and found that the œsophagus terminated above and below in blind rounded ends an inch and a half apart, and there was no cord or connection between the parts. All the wounded portions were quite healthy, and the appearances led to the conclusion that had there been only a membranous occlusion a happy result might well have been hoped for.

Electric Prostration.—Several cases of this peculiar malady are reported from France. It affects workers under electric light. The light exceeds 100,000 candle-power, and it would appear that it is this excess of light, and not the heat, which produces the nervous symptoms. A painful sensation in the throat, face, and temples is first noticed, then the skin becomes coppery red, and irritation is felt about the eyes; much lachrymation ensues, and these symptoms then disappear, while the skin peels off in five days. The effects are comparable to those produced by walking over fresh snow in the sunlight.

New York, December 15, 1888.

INGUINAL COLOTOMY FOR MALIGNANT DISEASE OF THE RECTUM.

In those cases of cancer of the rectum which come under the surgeon's care too late to justify any attempt at excision, the question of palliative treatment becomes an urgent one, for there are few diseases which entail a greater amount of horrible suffering than the one we are speaking of. Until recently, lumbar colotomy was the operation selected by most surgeons to afford the "temporary relief" which is all that our actual resources can hope to accomplish in this fatal malady. At the present time, however, inguinal colotomy is preferred by many to the lumbar method.

Mr. Harrison Criffs is the latest prominent advocate of the inguinal operation; he bases his views on a series of nine successful cases, which he has reported in the *British Medical Journal*, October 6, 1888.

Speaking of colotomy in general, the author says that it completely relieves all symptoms arising from the contracted state of the bowel, while it serves as a permanent safety-valve against the risk of complete obstruction. The influence of the operation in retarding the growth is a debatable question. His own impression, founded upon considerable experience, is a strong one, that the progress of the growth becomes much slower after the bowel is set at rest by the operation. The return of strength and the gain of flesh are often well marked after colotomy, no doubt due to the increased appetite, the relief from pain, and the quiet nights following the operation.

To suppose that a patient after colotomy is in a miserable condition, with fæces constantly running away from the opening, is a delusion. If, as sometimes occurs, the opening is made too small, or allowed unduly to contract, the advantage of the operation is, in great measure, lost. and constant dribbling occurs from the wound. If, however, care be taken to make the opening valvular and of sufficient size, a motion generally passes but once a day, and there is a fair amount of control over the new anus.

The time at which the operation should be performed is a matter of some importance. Dr. Criffs advises it without delay in cases where symptoms of stricture are present. If deferred, not only does the patient lose the advantage of the operation, but it may have eventually to be performed for complete obstruction under most dangerous and unfavorable circumstances. Colotomy on an empty bowel, when the patient is not reduced to death's door by unrelieved suffering, involves but slight risk to life.

It is known that the death-rate at a later period, when the bowel is already quite occluded, is very high, running up to fifty per cent.

The chief objection to lumbar colotomy is the difficulty at times found in certainly recognizing the colon, many good surgeons having opened the small intestine with evil results. Variations in the course of the descending colon may also lead the surgeon astray. "Slight variations in the course of the bowel generally mean nothing worse than a somewhat prolonged search; but not infrequently the operator altogether fails to find the bowel. The cause of this failure, as pointed out by Mr. Lockwood, arises from the bowel taking a totally abnormal course, so that practically there is no descending colon on the left side. To send the patient back to bed unrelieved, with a deep and dangerous wound, is a most unfortunate circumstance, but one which, nevertheless, is sure to occur in a certain proportion of cases."

Mr. Criffs points out that "inguinal colotomy meets both of the objections referred to. Owing to there being plenty of space, there is no difficulty in finding the bowel; for, should it run an abnormal course, and not present itself when the peritoneum is opened, the operator has only to pass his finger down toward the pelvis and feel for the upper part of the rectum, when the bowel can be easily traced upward, and a portion of the sigmoid flexure hooked out. Moreover, there can be no possibility of mistaking the small intestine for the large, the three longitudinal bands, together with the glandulæ epiploicæ, being so clearly marked and easily recognizable as to render a mistake impossible. From the operator's point of view there can, therefore, be no possible question of the superiority of the inguinal over the lumbar operation, especially if it can be shown that there is no disadvantage in the position of the outlet, nor that opening the abdominal cavity increases the risk of life."

The author states further that, as regards the risk of the operation, it is probably less than in lumbar colotomy. The bowel is found with ease and certainty; a clean incision can be made through the abdominal parietes without the bruising or damage of the subperitoneal fat so frequently unavoidable in Amussat's operation. The parts thus unite by first intention, with scarcely a trace of constitutional disturbance.

Dr. Criffs describes his method of operating as follows: "The abdomen having been thoroughly well washed with soap and water, antiseptic treatment as regards sponges, instruments, hands, etc., is carried out. An incision two inches and three-fourths in length is made one inch and a fourth from the anterior superior spine, one-third of the incision being above and two-thirds below an imaginary line drawn from the anterior superior spine to the umbilicus. In making this incision the skin should be drawn a little inward, so that the opening through the transversalis fascia and the peritoneum is on a different level, when the skin is again relaxed, thus making the opening valvular, and rendering its subsequent closure with a pad easier. The peritoneum being reached, it is pinched up and a small opening made, which is subsequently enlarged to nearly the length of the cutaneous incision. The small intestine generally first presents, but.

on pushing it back, the colon often shows itself; if it does not, it can be readily found by passing the finger downward into the pelvis, and following the rectum upward till the sigmoid flexure is reached, which can be hooked out with the tip of the finger. With moderate care there can be no possibility of mistaking the small intestine for the colon. The three longitudinal bands are very conspicuous, which, together with the glandulæ epiploicæ and the regular convoluted surface, establishes unmistakably its identity; not infrequently, moreover, hard, scybalous masses can be felt within it. A loop of bowel being drawn into the wound, two provisional silk ligatures are passed through a portion of the peritoneal coat opposite the mesenteric attachment. These provisional ligatures, the ends of which are six inches long, help to steady the bowel during subsequent stitching to the skin, and eventually serve as guides when the bowel has to be opened. They should be two inches apart. The bowel is now temporarily returned into the cavity. The parietal peritoneum is then picked up with forceps, and attached to the skin on each side of the incision, one inch and a half apart, by a couple of sutures of fine silk. The bowel is again drawn out by means of the provisional ligatures, and fixed to the skin and peritoneum by six fine ligatures on each side. These sutures are best passed by fine, partly curved needles, the needle passing first through the skin an eighth of an inch from the margin, then through the parietal layer of the peritoneum, and lastly through the peritoneal and muscular coat of the bowel. great care being taken to avoid perforation of its mucous membrane. It is easier to pass all the sutures before tying them up. The wound being perfectly cleaned by gentle sponging, the threads can all be tied with moderate tightness. A suture should now be passed through the skin at each end of the wound, including a portion of the peritoneal layer of the bowel."

The ligatures should be passed not far from the mesenteric attachment of the gut, so that about two-thirds of the circumference of the bowel is external to the wound. The author regards it as "waste of time stitching the parietal layer of the peritoneum all the way round to the skin before drawing out the bowel; the four stitches mentioned are all that are really necessary at first to fix it, for it is subsequently included in the ligatures attaching the bowel to the skin. A piece of green protective is put over the exposed bowel, and the whole covered with a firm antiseptic dressing. Unless the protective is used, it will be found that the lymph thrown out from the bowel has attached the dressings with surprising firmness." He dresses the case the next day "to make sure that nothing has been displaced by vomiting, etc., the dressings being reapplied and kept on till the sixth day, when the bowel can be opened. By this time it is found firmly attached to the skin, and covered by a remarkably thick layer of organized lymph. In opening the bowel the provisional threads which have been left in afford a valuable guide. They are gently drawn upon, and the bowel opened between them with a sharp knife. The cut margins of the bowel can be pared off with scissors to the level of its attachment to the skin. No anæsthetic is necessary, the bowel being quite insensitive. The patient is convalescent in about three weeks."

We have closely followed Mr. Criffs in his descriptions, because we regard his report of nine successful cases as a strong argument in favor of the inguinal method. Perhaps he goes too far when he says that in a few years lumbar colotomy will be a mere matter of history. But he has certainly put forward a plea in behalf of the inguinal method which no modern surgeon can afford to disregard.

IS THE PRACTICE OF MEDICINE A FAILURE?

This question might well seem superfluous, and even absurd, in the face of the fact that practitioners of medicine are increasing yearly at a tremendous rate, that new medical colleges are every year being organized, new drugs discovered, and innumerable new drug-stores getting upon a solid business basis.

Nevertheless, the inquiry is not an irrational or useless one, and it has a twofold significance; viz., in its relation to the physician and in relation to the public. Statistical investigations show, with regard to the first point, that a large minority of those who set out to practise medicine fail to make a living, and drop into some less learned but more lucrative pursuit. A fair proportion gain just a livelihood, a very few obtain some degree of honor and pecuniary reward. Now, the practice of medicine is a failure, relatively speaking, if those who set out fail to a degree out of proportion to the failures in other pursuits requiring equal time and expenditure of capital; as, for example, the law, engineering, artistic professions, and business. It is a failure also if the wear and tear of professional work are excessive in proportion to the pecuniary, intellectual, and moral returns.

To this question we offer no positive answer. We are inclined to take the optimistic view of life as nearer the truth; but we may remind our readers that the limit of life of medical men is lower than that of most other professional classes; and that medical men, with few exceptions, die poor.

What can be said as to the success of our art in its application to the relief of disease? We exclude, of course, surgery and hygiene, and assume only that the question, "Is medicine a failure?" relates to the application of drugs and other remedial measures to actual disease. We have lessened the number of infective and septic disorders; but, when they attack an individual, are they any more perfectly under control? We refer our readers to the discussion on the mortality from pneumonia, which is asserted to be greater now than it was half a century ago. The mortality from diphtheria, scarlet fever, typhoid, phthisis, is somewhat lower than it used to be, and a vigorous defence of modern therapeutics might be made in connection with these and a number of other common diseases. We must bear in mind, however, that the question is one that must be answered with reference to society in general rather than to the individual. And though we pull many weakly patients through attacks of illness by aid of modern therapeutics, is not the result an increase of invalidism which tends to propagate itself, producing in succeeding generations an oversickly race?

It is quite safe to discuss the question, "Is the practice of medicine a failure?" for, however plainly its inutility may be shown, people will continue to seek relief from bodily ills. Civilized man is bound to marry and bound to be doctored for a very long time to come. All the same, the exact economical value of matrimony and medicine may be the legitimate object of impartial inquiry.

THE AMERICAN SURGEON ABROAD.

We regret to learn that some of our medical countrymen who go abroad for instruction and amusement have been found to exhibit an extraordinary lack of good taste and good manners. The evidences are, unfortunately, but too plainly given in the form of published letters to their local journals. It seems as though it should be obvious to every one that when a physician is invited to the wards or clinics of a surgeon, any after-criticisms made, if made at all, should be of the most general and non-personal character. One does not expect his dinner-guest to go home and babble of hitches in the domestic arrangements that may have come to his notice. Just as much should be expected of the guest of a hospital surgeon.

We are led to write the foregoing after the perusal of a not very edifying controversy between Mr. Lawson Tait and a Chicago surgeon, who was denied admission to Mr. Tait's clinics. The Chicago surgeon in question comes out in an article entitled, "Why I did not see the Birmingham Spayer," and claims that he did not receive courteous treatment from the said ovarian artist. Whether or not our countryman was rightly treated we cannot say; but judging from comments made by him upon the surgical work of others to whose clinics he was invited, we should say that Mr. Tait was somewhat lucky in escaping his critical presence. Here are some of his "impressions," as printed in the *Western Medical Reporter*:

Of Mr. Treves he says: "He is rather a careless antiseptician." Of Mr. Christopher Heath: "Rather given to profanity if matters don't go to suit him." Still another: "I saw Mr. Knowsley Thornton operate upon a unique case in rather a bungling manner." Yet another: "At my final visit I saw a most interesting case of hemorrhagic cyst of the pancreas. Stephen McKenzie regarded it as an abdominal lipoma. Treves thought it to be a sarcoma, and I made bold to suggest to him in the ward . . . the strong probability of its being a pancreatic cyst. . . To my delight, it proved to be, as I predicted, a cyst of the pancreas. At his next clinical lecture Treves gave a very complete review of the literature of pancreatic cysts, omitting to mention, however, the recent American cases of Bull, Fenger, and my own. . . . He was of the impression that a correct diagnosis had never been made prior to the operation. I took occasion to supply the omissions and correct his misapprehensions on the subject in a personal letter."

SNOW-BLINDNESS.

The symptoms of snow-blindness are not unknown to those practising in rural districts in the extreme northern parts of this country. They consist of a certain degree of conjunctivitis, or conjunctival irritation—as if there were a foreign body in the eye—blepharospasm, and photophobia. In the later stages there is not infrequently a certain degree of chemosis. The condition is usually regarded as the result of the combined influences of the intense sun-light reflected from the surface of the snow, irritating the retina, and of the cold, and often rarefied, air striking upon the conjunctiva.

Dr. August Berlin, of Stockholm, writing in the *Nordiskt Medicinskt Arkiv*, vol. xx., No. 3, 1888, proposes a new theory in explanation of this condition. The author accompanied Nordenskjöld in his expedition to Greenland in 1883, during which he had frequent opportunity to observe the affection. The geographical distribution of the affection is very characteristic, as it follows closely the isothermal lines in the three continents bordering on the north pole, coming farther south in America and Asia than it does in Europe. The disease is also met with in very elevated regions, even down to the tropics. When occasionally seen in temperate regions, it is usually milder in degree. The time of the year in which it is most common in northern latitudes, according to the author, is the spring, although it may occur also during the summer. It usually affects but one eye, and that eye is the one which has been most exposed to the direct rays of the sun. It is upon this fact chiefly that Dr. Berlin bases his theory of the causation of the disease.

The regions in which the affection occurs are characterized by an intensely cold air and a low degree of humidity. As it is the humidity of the atmosphere that absorbs the heat of the sun's rays, they ought to exert a more intense action here than in lower latitudes. And that this is the case is evident by the fact that the exposed skin suffers more from the action of the sun than in other regions, a very painful dermatitis being frequently caused by even a short exposure to the sun. Now, snow-blindness, according to the author, is due to the same cause, and the process in the two cases is the same, viz., hyperæmia and then exudation, accompanied by an intense burning sensation. Erythema of the conjunctiva is the name given by Dr. Berlin to the condition known as snow-blindness, and that it is primarily an affection of the conjunctiva rather than of the retina, is shown, he thinks, by the fact that it is caused by the irritation from the fine particles of snow during a blizzard as well as by the sun's rays.

The prophylactic treatment which the author proposes is simply a modification of the "snow eyes" used by the Esquimaux. Instead of a disk of thin wood with a minute transverse slit in its centre, he recommends goggles made of a moderately fine wire network without glass.

A PLEA FOR INDIGESTIBLE FOOD.

Sir William Roberts, we believe, is responsible for saying that one function of alcohol in digestion was to slow the process so that food would not be too quickly absorbed. In a recent issue of the *Dietetic Gazette* Dr. Sara E. Port advances the ingenious theory that digestibility is not the sole, or even the best, test of food in making up a diet. Easily digestible food taken in considerable amount floods the blood and tissues with excrementitious matter. The excess of peptones taken in a meal appears in the urine within an hour (Voit), and evidently can have done little benefit to the economy. Dr. Port cites the case of a patient who travelled extensively, and who always became hungry before noon on an ordinary breakfast of chops or steak. So that when setting out on a journey she depended on ham, hard-boiled eggs, and other food usually considered indigestible.

The writer adds: "The laboring man acts upon a similar plan. In spite of recommendations in regard to soft-boiled eggs, broiled steaks, farinaceous puddings, and rare roasts, the workingman prefers and demands what he calls hearty food. ' This means usually hard-boiled eggs; fried steak—the harder and crisper the better; beef roasts, well-boiled ham; corned beef; pork; baked beans, not too well done; potatoes with a core; suet puddings, and pies."

One might detect an admirable socio-economic arrangement on the part of Providence in the poor man's dietary as thus described. Hearty food is cheaper, and, as it seems, it is also better for him. The attempt to eliminate the frying-pan and introduce high art into cookery is really, therefore, a subtile assault upon the health and happiness of the working-classes.

Dr. Port writes: "The body is an engine for which the stomach is the coal-box. He would be a bad fireman who would empty his coal-box into his furnace all at one time. He would get up a rousing fire undoubtedly, but if he had to wait six hours before replenishing his coal-box his engine would probably come to a stand-still on the road. The wise fireman puts in a little coal at a time and replenishes often. If one has six hours between meals, and continuous effort to provide for, it would be poor policy to put into the stomach food which would digest completely in two hours' time. The laboring man will never agree to such a reform. His present diet is suited to his needs. Even the frying process cannot be logically objected to."

The author concludes:

1. Digestibility is not a complete test of food-value.
2. Proteids are of the most value when limited in quantity and of the less easily digested forms.
3. Limitation of proteid food is particularly indicated in Bright's disease.
4. The sphygmograph furnishes important evidence in the prealbuminuric stage of this condition.

Finally, "predigested foods" and "easily digested foods" should be reserved for cases in which the digestion is in fault. The value of such foods in the management of the pathological conditions of the digestive tract is beyond question.

A STUDY OF LONGEVITY IN NEW ENGLAND.

Mr. Clement Milton Hammond has made an interesting contribution to the subject of longevity in a recent issue of the *Popular Science Monthly*. Mr. Hammond, as an associate editor of the Boston *Globe*, had peculiarly good opportunities for making a collective investigation regarding the old people of New England. He sent out 5,000 blanks to all parts of the section in question. These blanks contained a variety of questions concerning age, sex, nationality, social condition, habits, temperament, occupation, etc. He had the unusual good fortune to get over 3,500 blanks filled out and returned. The answers were from every county in Massachusetts, and nearly every county in New England.

Mr. Hammond has analyzed these returns, and for the most part has shown care and judgment in so doing. He does not seem to be aware, however, of the similar work done, much more thoroughly, by the British Collective Investigation Committee, and his own labors would no doubt have been helped by a wider knowledge of previous work in this line.

We present some of the data which were obtained.

As to social condition, over ninety-five per cent. had been or were married.

The number of women slightly exceeded the men.

The marriages had generally been fruitful, the average number of children being five.

Five out of six of the old people had light complexions, with blue or brown eyes and abundant brown hair; being probably of the nervous-sanguine temperament. The men were "mostly tall." (Mr. Hammond is uncommonly vague in many of his statements.) They were thin, bony, and muscular, while the women were plump. The men varied in weight from 100 to 160 pounds, and the women from 100 to 120 pounds. The men could not be so very tall, therefore, or the women very fat.

As to habits, the rule was almost universal that the old people had gone to bed early and got up early. This was also found to be the case by the British committee. Their meals had been eaten regularly, the dinner hour having been usually at noon.

As to occupation, out of 1,000 men over eighty years of age, 461 were farmers, 92 carpenters, 61 mariners, 49 laborers, 42 shoemakers, 41 manufacturers, 23 clergymen, 12 physicians, 12 lawyers, 23 masons, 16 blacksmiths, 16 bankers.

This list, however, signifies nothing, except that nearly half the answers to the blanks were from farmers.

Eight hundred out of 1,200 women were farmers' wives. The diet has been the ordinary New England fare, of pork, beef, fish, vegetables, "almost always poorly cooked,' with pies, doughnuts, and cakes.

Two-thirds of the number drank tea and coffee habitually, and nearly all drank tea.

"Very few" used alcohol, but a large proportion of the men used tobacco.

About one-third of the men, and nearly the same proportion of women, had never been ill since childhood.

About one-fourth of the children of the old people were still living.

Mr. Hammond notes the fact that most of his returns showed that the old people were employers rather than employees, and he draws the conclusion that a certain amount of responsibility tends to prolong life. He is disposed to lay some stress on the value of the nervous-sanguine temperament as a factor in longevity.

Hypnotism at Berlin.—A certain Dr. Feldmann, who is not, we believe, a qualified medical man at all, has been exhibiting his attainments as a hypnotizer and mind-reader before the Berlin Medical Society. He showed all the familiar performances of "subjects." It is interesting to note the progress of medical opinion. Dr. Feldmann could not get before a reputable medical society when in this city last winter; but in Berlin he has appeared before the leading medical society, presided over by Professor Virchow.

News of the Week.

UNFORTUNATE ISSUE OF AN ATTEMPT TO TRANSPLANT A RABBIT'S CORNEA.—Miss Mary Fisher has sued Dr. L. W. Fox for malpractice in transplanting a rabbit's cornea to her eye. She lost what sight had previously existed in that eye. She claims that she was not informed as to all the possible results of the operation.—*Medical Standard.*

THE UNIVERSITY OF MARYLAND MEDICAL MUSEUM ASSOCIATION has been formed, with the following officers: *President,* Professor J. Edwin Michael; *Vice-Presidents,* Dr. Herbert Harlan, Dr. R. B. Warfield; *Pathologist,* Dr. C. W. Mitchell; *Curators,* J. G. Van Marter, Jr., R. A. White.—*Maryland Med. Journal.*

TO INVESTIGATE DISEASES OF SWINE.—The Commissioner of Agriculture has appointed a commission, consisting of Professor William H. Welch, of Johns Hopkins University, Dr. E. O. Shakespeare, of Philadelphia, and Professor T. J. Burrill, of the University of Illinois, to investigate the subject of swine diseases in the United States and the methods of their treatment and prevention.

DISINFECTION AFTER INFECTIOUS DISEASES.—The city of Berlin has a provision by which persons who wish their houses, rooms, or clothing disinfected after the occurrence of infectious diseases can have it done at a moderate cost. The number of applications for disinfection increases yearly, and in 1887 amounted to nearly two thousand.

JUVENILE SMOKING.—Owing to the increase of juvenile smoking in this country, the Society against the Use of Tobacco has taken steps to obtain a law to prevent children from smoking. It founds its arguments on a series of observations which have recently been made. Of thirty-eight young smokers, aged from nine to fifteen years, it was found that twenty-seven experienced a certain degree of malaise, and twelve, seriously affected, had contracted the germs of grave maladies.

IS THE RACE DEGENERATING?—An English lay journal has been making a collective investigation regarding the questions given below: "1. Does your experience suggest to you that the race of Englishmen is degenerating physically? 2. Do you think that the great advance in the healing art is responsible for keeping alive much weak life that will in time affect the whole race injuriously? 3. Do you think that the increased indulgence in physical sports has, on the whole, a good influence on health? 4. Has it ever struck you that probably the great attention paid to health in these days may be producing an anxiety about bodily ailments which is a disease in itself?" Answers have been received from a long array of practitioners, among whom are the names of eminent London physicians. The general view taken is that Englishmen are not degenerating, but that, on the whole, the race is improving in vigor.

NAVAL SURGEONS AND LOCAL PRACTITIONERS.—Washington despatches state that a petition was sent recently to Secretary Whitney, signed by fourteen of the practising physicians of Pensacola, which complained against Surgeon J. W. Ross, attached to the Pensacola Navy Yard. The petition charged that Surgeon Ross was guilty of unprofessional and unofficer-like conduct; that although he was receiving a large salary from the Government, and was living in quarters furnished by the Government, he was actively engaged in prescribing for numerous civilian patients at the Government dispensary, where he had the free use of medicines and instruments, and that he assisted other patients at Government expense and accepted less than the schedule rate of fees charged by his professional brethren, thus diminishing their practice and revenue therefrom. The petition was referred to Surgeon Ross, who, while denying the right of the petitioners to meddle with his affairs, admitted that he treated and prescribed for patients from distant points, took fees from those who were able to pay, and gave his services and medicine free to those unable to pay, especially to those on the Naval Reservation. He denied the allegations that he used Government time, appliances, or medicines for those not entitled to them, and upon the testimony of others that Surgeon Ross had simply given his services out of sympathy for the poor, and had done much good, the Secretary refused to interfere.—*Boston Medical and Surgical Journal.*

AN ESTEEMED Western contemporary gives the following useful and phonetic advice: "A minute potion of striknia is recommended to cure flatulend dispepsia."

DR. MAURICE NORTON MILLER, a well-known physician in this city, died on Saturday, December 8th, at his home, in the fiftieth year of his age. He graduated from the University Medical College in this city, practised for a number of years in Philadelphia, and sixteen years ago returned to this city. He accepted a position as lecturer in the college from which he graduated, and has recently been connected with the Loomis Laboratory, lecturing upon microscopy. He was also special pathologist to the Ward's and Blackwell's Island institutions. He was a member of the County Medical Society, and at one time Secretary of the Medico-legal Society. He had recently written a valuable work on histology.

A HOSPITAL CONSECRATED.—St. Joseph's Hospital for Incurables, One Hundred and Forty-third and One Hundred and Forty-fourth Streets, was consecrated by Archbishop Corrigan, Wednesday morning. The hospital will probably be open for the reception of patients in about two weeks. The building was begun about a year ago last spring and has cost about two hundred and seventy-five thousand dollars, the money being raised by contributions ranging from ten cents to one thousand dollars or more. Consumptives are expected to be the especial patients of the institution, though there is no rigid discrimination against patients of other sorts, and none whatever on account of creed, sect, or religion.

COLLEGE OF MEDICINE FOR THE CHINESE, HONG KONG.—The first professional examination of the College of Medicine for the Chinese, Hong Kong, was held during the second week in August. The subjects of examination were botany, chemistry, physics, elementary anatomy, elementary physiology, materia medica (first examination), and clinical observations. The written examination extended over four days; and the *vivâ voce* examination, held in the City Hall, was open to the public. Twelve students presented themselves for examination, of whom seven passed. Two scholarships, of the value of sixty dollars a year, were awarded to the first students on the list.

Pneumonia-mortality in Massachusetts Almshouses.—As a slight contribution to the further study of mortality from pneumonia, a consideration of some figures derived from the reports of the three State almshouses in Massachusetts may prove of interest. In the Monson Workhouse the death-rate for the decade 1856 to 1865 was 21.09 per cent., while for the decade 1866 to 1875 it had fallen to 16.43 per cent. Since 1872, when the institution was converted into a State primary school, the adult paupers being sent to the State almshouses at Bridgewater and Tewksbury, pneumonia has been so infrequent among the children as practically to be absent. At any rate, no comparison is possible with the data of the previous decades.

Of the Bridgewater Workhouse we have data at our disposal since 1861. For the five years from 1861 to 1865 the death-rate from pneumonia in this almshouse was 27.44 per cent; for the decade 1866 to 1875, 28.12 per cent., and for the decade 1876 to 1885, 36.58 per cent., showing a small though steady increase. From the Tewksbury State Almshouse the reports are more complete, showing for the decade 1856 to 1865 the very low rate of 13.95 per cent., for 1866 to 1875 the large rate of 36.25 per cent., and for 1876 to 1885 the still larger rate of forty per cent. Eliminating, however, as years of exceptional mortality, the year 1874, when of twenty-six patients fourteen died; the year 1875, when out of thirty twenty died; and the year 1885, when of eleven patients all died, we get a death-rate for the three decades of 13.95 per cent., 23.07 per cent., and 34.67 per cent.—*Boston Medical and Surgical Journal.*

"The Doctor's Wife."—A correspondent writes to the *British Medical Journal:* "Dr. A's wife is requested by mutual friends to call upon some new residents in the neighborhood in which she lives. She does so, and a pleasant acquaintanceship ensues. Dr. B is offended, and when asked why, declares that A is guilty of a breach of medical etiquette, inasmuch as his wife, who represents himself, has called upon people other than her husband's patients. Is Dr. B justified in his opinion, and are all professional men's wives debarred from increasing and renewing their social circle for fear of being considered guilty of touting?" In response to "Cosmopolitan's" question of etiquette in the above case, the *Journal* quotes the following foot-note from the "Code of Medical Ethics" as an apposite reply, saying that from it he could readily deduce the medico-ethical moral it inculcated in relation thereto: "Closely akin to solicitation is that of calling upon new residents in the neighhorhood and leaving their card, ostensibly as a mark of respect, but in reality to seek for practice. It cannot, therefore, be too deeply impressed upon such that the true dignified practice, and the most consistent with a due respect for self and the faculty, is to wait until their professional or social acquaintance is sought; in such case, moreover, it is far more likely to be appreciated."—*British Medical Journal.*

Our Brilliant and Poetic Contemporary, the *Weekly Medical Review*, places us under obligations by the following annotation: "As these notes, which have been jotted down at odd intervals, are being closed, the New York Medical Record, of November 17th arrives, along with other exchanges, and it is among the first read, as it certainly ranks among the first of the medical journals of America; and I am prompted to say that if its able, enterprising, and erudite editor will attend, during the coming year, one session of the McDowell Medical Society in Kentucky, or the Mississippi Valley Medical Association, either in St. Louis or Evansville, in the side pocket of Indiana, I promise him that he will be more disposed to feel that life is worth living, his gray matter will be as active, his perceptions as keen, and the shining disks of blood which go coursing through his arteries and veins will carry a more perfect grade of hœmoglobin, and be permeated with the glow of sunshine and good cheer, and his scientific acumen will be not in the least impaired." We cannot but think that our esteemed contemporary circulates six million blood-corpuscles to the cubic millimetre instead of a paltry five; but he should spell his hæmoglobin with "ae."

Women and the Study of Medicine.—Professor Waldeyer, of Berlin, read a paper recently before the Assembly of German Naturalists and Physicians at Cologne, in which he exhaustively reviews the rôle of women in the study and practice of medicine, going back to antiquity, and bringing forward a curious array of historical facts through the Middle Ages down to the present time. His conclusions are not favorable to the "women doctors." Among the objections which he raises are the following: "The profession, and especially 'the faculties' will be overcharged; men capable of doing great things will keep out of medicine. This will be an enormous loss to science, for women are good for nothing as experimenters or original workers. In the laboratories they are awkward, careless, and unskilful." He emphasizes the usual stock arguments as to the "separate spheres" of the sexes, and concludes: "We should take care how we encourage the tendency of women to enter upon the study of medicine. It is not the way which will lead to the amelioration of their lot. If the medical profession is open to them, the other learned professions must follow in their turn. Hence there is sure to result a fierce and bitter struggle, in which our entire humanity will succumb."—*Boston Medical and Surgical Journal.*

The Inhabitants of New York One Hundred Years ago and their Doctors.—From some recently published records of New York City history, one hundred years ago, we gather the following interesting statement: "The inhabitants of this colony are in general healthy and robust; taller, but shorter-lived than Europeans; and, both with respect to their minds and bodies, arrive sooner to an age of maturity. Breathing a serene, dry air, they are more sprightly in their natural tempers than the people of England; and hence instances of suicide are here very uncommon. Few physicians among us are eminent for their skill. Quacks abound like locusts in Egypt, and too many have recommended themselves to a full practice and profitable subsistence. This is less to be wondered at, as the profession is under no kind of regulation."

Treatment of Erysipelas.—Nussbaum recommends the application of a pomade of equal parts of lanolin and ichthyol as a very speedy and simple method of cure in erysipelas. He covers the parts with salicylated cotton, and obtains a painless cure usually in two or three days.

Dr. Atlee on Lacerations of the Cervix.—Dr. Walter F. Atlee has recently written the following to the *Pittsburg Medical Review:* "Some thirty years ago my old master, Nélaton, told me that certain diseases of the neck of the womb were *le paturage des charlatans.* Since then this pasture ground has become much more extensive; it extends to the womb itself and to all its appendages, and many grow fat therefrom, to whom we dare not apply the epithet of charlatan. In medical journals a few weeks ago I read that Noeggerath recommends that tears in the neck of the womb should be left alone. He says that they have no influence on the development of uterine disease, either as to intensity or frequency, and that diseases of the tissues of the cervix are not more frequent in lacerated than in uninjured cervices. My father. Dr. Atlee, of Lancaster, practised medicine some sixty-five years; he attended himself 3,264 women in childbirth, and had a very extended practice as a consultant in affections of the female genital organs. Shortly before his death, after I had been in practice some thirty-five years, he asked me if I had ever found it advisable to sew up the neck of the womb for a tear. My answer was, No. 'Nor have I,' said my father. Sixty-five years and thirty-five, or a whole century of active professional work, and not one case where it was thought advisable to perform this operation. And, more than that, not one case where there was any reason to regret its not having been performed. Mankind are, indeed, fearfully at the mercy of practitioners of medicine. How necessary it is that those who become such should recognize that they are undertaking high responsibilities and difficult duties. A celebrated author wrote many years ago that the physician without a conscience was as much to be dreaded as a highway robber. It may be that he is more to be dreaded; the highway robber says, 'Your money or your life,' and the other may take both."

The Secret of a Laparotomist's Success.—Mr. Tait does not adore the Germans, and avers that the time he has spent in learning German has been a dead loss. Some time ago a celebrated German surgeon visited him and asked Mr. Tait the secret of his surgical success, Mr. Tait looked at his German visitor's hands and hesitated at first to answer. Finally he replied, "It is because I give the greatest attention to the care of my nails." The German looked at his own nails and turned away. He never called again.

Sir Morell Mackenzie and Professor Virchow.—The *Freisinnige Zeitung* of Berlin recently stated that Professor Virchow has received numerous requests from various quarters to give a judicial summing-up of the case of the late Emperor Frederick, embodying his opinion on the whole subject, as presented both by the German physicians and surgeons and by Sir Morell Mackenzie. Virchow has quite recently shown his impartiality in the matter by declaring certain of Sir M. Mackenzie's statements to be incorrect, and also some of Professors Gerhardt and Bergmann to be either incorrect or not proven. Herr Eugen Richter, the editor of the *Freisinnige Zeitung*, remarks that Professor Virchow's observations to the representative of a journal who recently "interviewed" him were made entirely on the basis of extracts published by that journal. These extracts, adds Herr Richter, were, however, recognized by Professor Virchow to be misleading when he saw Sir Morell Mackenzie's book. According to the *Vossische Zeitung*, Professor Virchow has made a further statement, regretting that more care and time had not been given to the drawing-up of the protocol of the *post-mortem* examination, and saying that he and Dr. Waldeyer had afterward wished to give it a more perfect form, but could not get permission to do so from the Royal Haus-Ministerium.

Menthol in Laryngeal Phthisis.—Dr. A. Rosenberg reports the results of twenty cases of laryngeal phthisis treated by menthol. All of these twenty, however, improved under treatment. In nine, actual recovery took place, *i.e.*, the infiltrations disappeared, the ulcerations cicatrized, and existing subjective troubles vanished. In all the cases the diagnosis was confirmed by the presence of bacilli. The most rapid in healing are the ulcerations, but of these the most obstinate are those on the posterior laryngeal wall. Infiltrations are more resistant, but they often diminish gradually. Commencing perichondritis on the arytenoid cartilages often disappears entirely. The duration of the treatment is from four weeks to four months. A comparative test of the action of menthol and of lactic acid was made in a case of tubercular ulceration of the velum palati, one-half of the palate being painted with either drug. The menthol side healed more rapidly, and was much less painful than where lactic acid was applied. In phthisis pulmonalis Rosenberg recommends tracheal injections of a ten per cent. solution of menthol in olive-oil, combined with frequent inhalation of the drug, by means of a special inhaler, which vaporizes the menthol, and allows it to be inhaled at a temperature between 40° and 50° C. He cautions against the use of any but Asiatic menthol, and considers that this drug is as efficacious as lactic acid, while at the same time it is more easily applied. One hears with some incredulity of the cure of over forty per cent. of cases of a disease that has generally been thought almost incurable.

The Therapy of Alcoholism.—Professor Forel, of Zurich, favors decidedly the total abstinence movement, and thinks that temperance societies are of great help in keeping many alcoholics from relapse. Forel believes in treating alcoholics by removal from all temptation to drink, the use of hypnotism (suggestion), and he would not ignore the helps of religion. Of 34 cases treated in the past two years 10 were intractable; 5 relapsed after improvement, 1 became insane, in 8 the result was unknown, 10 had continued well up to the time of reporting. Hypnotism was tried in 12 cases. Dr. Forel's record bears evidence of being an honest one, and shows about the percentage of cases that may be expected under the best treatment.

The Opening of the Hoagland Laboratory, Brooklyn, N. Y.—The Hoagland Laboratory will be opened on Saturday evening, December 15th, by Professor H. Newell Martin, M.D., of the Johns Hopkins University, who will deliver an address at eight o'clock, after which the Laboratory will be open for inspection. The profession and friends are invited to be present. Cornelius N. Hoagland, Charles H. Hall, Joshua M. Van Cott, Charles E. West, Joseph H. Raymond, Trustees.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 6, 1888.

Abraham Jacobi, M.D., President, in the Chair.

Nominations being in order, the President remarked that during his four years of service he had earned the credit, he believed, of not interfering in the business of the Academy more than the presiding officer should do. His deep interest in the welfare of the institution was the only apology he had to offer in exercising his right as a member on this occasion to nominate Dr. Alfred L. Loomis for the office of President.

Dr. Jacobi declined a re-nomination.

For the office of *Vice-President* the following nominations were made: Drs. E. G. Janeway, Francis Delafield, and D. B. St. John Roosa. For *Recording Secretary*, Drs. A. M. Jacobus, N. J. Hepburn, and Richard Kalish, who declined. *Corresponding Secretary*, Drs. M. A. Starr, F. P. Kinnicutt, and H. J. Garrigues. For *Treasurer*, Drs. O. B. Douglas, Daniel Lewis, and W. F. Cushman. For *Trustee*, Drs. A. Jacobi, Laurence Johnson, J. E. Janvrin, H. D. Noyes, and Hermann Knapp. For *Member of Committee on Library*, Drs. E. H. Grandin, M. A. Starr, and E. S. Peck. For *Member of Committee on Admissions*, Drs. T. R. French, of Brooklyn, Robert Abbe, Charles Jewett of Brooklyn, and T. H. Burchard. *Delegates to the State Medical Society* (six to be elected), Drs. C. A. Powers, F. H Bosworth, R. C. M. Page, F. N. Otis, R. F. Weir, A. Caill·, S. Baruch, F. P. Kinnicutt, J. Fruitknight, William Stevens, A. Seibert Westbrook, of Brooklyn, J. E. Weeks, and H. C. Coe. For *Treasurer of the Board of Trustees*, Dr. F. A. Castle.

Dr. J. R. Leaming then read a paper entitled,

ACOUSTICS APPLIED TO THE HUMAN CHEST, IN PHYSICAL DIAGNOSIS.

Since the application of the laws of light to the study of the eye ophthalmology had become the one branch of medicine entitled to the distinction of being scientific and consequently certain. Optics and acoustics were twin-sister sciences; the laws of one which were familiar had ever been used in the elucidation of the obscure in the other. Yet while optics had been successfully applied in diagnosis of diseases of the eye, acoustics had hardly been thought of as a sure solution of the problems of diagnosis in diseases of the chest. The author believed the reason for this was the fact that until lately acoustics had been an unapplied science in medicine. Laënnec, who discovered the means of diagnosis by auscultation and the stethoscope, and Louis, who did so much to make them practical, were not learned in acoustics. The brilliancy of the discovery of Laënnec and its great possibilities blinded the eyes of the profession then and since, so that auscultation had just missed being perfect by not being based upon eternal law. Skoda made a step toward this consummation when he discovered the principle of consonation.

In this practical age of the application of the laws of sound to the telegraph, telephone, phonograph, and microphone, it became easy to apply acoustic law to the diagnosis of diseases of the chest.

All sound originates in vibrations which pass through the air in waves, the same as light. The rapidity of the vibrations gave pitch, and were limited in recognition by the human ear practically to between 32 and 1,700 in a second. Less than 32 vibrations in a second, gave the idea of distinct sounds, while more than about 1,700 resulted in silence. These two fundamental principles in acoustics were essential in studying the physical conditions of the chest.

The chest was a chamber encompassed by walls, the inside of which was lined with a dense elastic smooth membrane, the costal pleura. The chamber had but little movement in the upper part where there was but little cartilage, but expanded largely at the base where cartilages were attached to the ribs. The cavity was closed in at the base by a diaphragm of muscle and tendinous expansion, which had great power of expansion and contraction, while ever continuing a perfect acoustic chamber in mathematical form, it could be enlarged or contracted; and consequently its power be augmented or diminished with the speed of thought. The upper and unyielding part of the chamber was a cone, and above it in the trachea was the sound box, the larynx, where the vibrations were primarily formed and conducted through tubes in every direction to the chest-wall, where they were reflected again and consonated into harmonious sound, and coming back were emitted through the larynx and mouth into the open air as music. The acoustic chamber of the chest in health was a perfect instrument for the formation and reflection of sound-waves, but it was liable to be altered in shape, and its acoustic perfection destroyed by changes of form from intrapleural adhesions, pressure of tumors, disease of the spine, etc.

The chamber was also filled with the lungs, heart, and their appendages, which interfered with sound-waves. The membranes in which the capillaries were spread out in sacs and minute tubes filled with alveoli were thin, diaphanous, and distensible to a wonderful degree, and yet it contracted down upon the contained air with force in alternate movements in which the air itself was an active factor. The acts of the heart and lungs were rhythmic, and were accomplished with sound, the heart-beat, and respiratory murmur. The auscultator had to give to each its due importance. The arrangement of the tubes and sacs in the lungs also constituted an acoustic instrument, but of a different kind from that of the chest-chamber. Each sac was a resonator distended by air constantly rarified by heat, upon which it constantly contracted, causing vibrations which helped to make up the vibrations of the true respiratory murmur. Each sac was connected through a bronchus with the outside air, and consequently sound-waves in the open air passed in and were consonated in each sac, as were also the friction vibrations of the tidal air rushing in and out through the open bronchi.

There were three sources of vibrations going to make up the respiratory murmur, and each one could be distinguished by the ear. When the chamber, or its contained system of tubes and consonating sacs, lost acoustic perfection it pointed to disease. The lungs could originate sound-vibrations in the air-sacs only when in perfect condition, or when the walls of the sacs contracted upon the contained air with muscular sound-vibrations, called muscular sussurrus, which was consonated in the compressed air of all the sacs into a body of sound. They might also receive vibrations from without, or from friction of the moving air within the tidal space of the connective system down to the fourth division of the bronchi. The tidal air-space, where the bronchial tubes had cartilaginous rings to keep them open, was the location of friction sound. This friction sound and the sound-waves in the open air were consonated in the air-sacs. The distance between the tidal air-space and the air-sacs was filled with compressed air, confined in distensible tubes connected with the air-sacs, but the air-waves from above were not consonated in them, but passed through and were consonated in the sacs. This was an acoustic fact of importance, for where unusual sounds came from the true respiratory system it was caused by conduction of pathological products.

The author then considered acoustic laws as related to the heart. The heart's action from the first was rhythmical. The lungs pressed against the inner wall of the chest during full inspiration everywhere except at the apex-beat area, which was occupied exclusively by the heart in health. The lungs constituted a perfect conductor of sound in the direction of their columns of air in tubes, but were non conductive in any other direction. They shut off all sound coming from the heart, except by natural direct conduction through the mediastinum, in all parts covered by them. If the cardiac sounds were heard otherwise through the lung substance it was acoustic evidence of compression, consolidation, or adhesion of the lung.

After further consideration of the anatomy of the heart the author went on to say that the auricle and ventricle in action were one. If it were not for the closure of the semilunar valves by the return shock of blood in the arteries there would be no mystery in the sounds and intervals of silence in the cardiac cycle. There would simply be contraction and relaxation—one sound and one interval of silence. The study of the heart's rhythm was entirely acoustic, and its right apprehension was of far more importance than all the other signs together, for there could be no alteration of the rhythm without pathological cause, whereas murmurs might mean little or nothing. Regarding the origin of the second sound of the heart there was no dispute. Not so regarding the first. Dr. Leaming was now more convinced even than twenty years ago of the correctness of the following explanation which he then gave. The curtains of the semilunar valves were floated up to the closure of the auriculo-ventricular system, but without force, for as yet there was no contraction; then, like a flash of lightning, contraction commenced in the auricle, instantly passed down into the ventricle, and the valves were forcibly closed. The stretched and vibrating membrane of the valve gave a drum-like sound of low note, the chordæ tendinæ were also thrown into vibrations in harmony with the valve, but of higher pitch. As the contraction of the heart went on the valve-note grew less, and the higher note of the chordæ increased until the apex struck the chest-wall and relaxation commenced. Repeating, he said, the first sound was formed by the vibrations of the tense mitral valve, by the tense chordæ, the sound of muscular contraction, and the friction of the blood. If it lost the valve sound, the low drum-like note, we knew that the vibrating power of the valve was affected. If it lost the higher note of the vibrating chordæ we knew that they were affected pathologically. What was left of the first sound was of blood friction and muscular contraction.

Dr. Leaming then gave a brief description of the organ of hearing as it concerned the auscultator; the binaural stethoscope of Camman was in mechanism the most perfect instrument for artificial auscultation, but for accuracy, delicacy, and freedom from acoustic imperfection or injury from outside sources nothing equalled the temporal bone placed against the sonorous object The whole side of the head was sensitive to vibration delivered directly from a sonorous body, but the most sensitive part was in front of and just above the external ear.

Dr. A. L. Loomis, being asked to open the discussion, said the paper was certainly a finished production as far as it went. While he had listened attentively and thought he comprehended its full significance, yet it was one which was suggestive and required study. The author had carried his auditors down to the practical application of acoustics in diagnosis of diseases of the chest.

He first obtained definite ideas regarding the laws of acoustics during his junior year at college under Professor Jackson, who stated that there were fourteen elements of sounds which could be appreciated by the aided ear. But of these Dr. Loomis had found only a few of practical value in auscultation; they were, pitch, quality, duration, and rhythm. These four qualities of sound could be easily appreciated and carried into every-day work. Of these he regarded pitch and quality as most important in diagnosis, and yet most difficult to fully grasp. He had long been familiar with Dr. Leaming's views regarding the part taken by the air-sacs in the production of the respiratory sound, through consonation, but he had been unable to distinguish this from the other elements of the respiratory murmur.

He could emphasize what the author had said regarding the importance of the cardiac rhythm. The more he studied diseases of the heart the more firmly he became convinced that it was the slight changes in the rhythm that pointed to pathological conditions rather than murmurs alone.

Dr. Leaming stated that it would have unduly lengthened his paper to have given the practical applications of the acoustic principles discussed.

SECTION IN GYNECOLOGY AND OBSTETRICS.

Stated Meeting, November 22, 1888.

Dr. J. E. Janvrin, Chairman.

AN INEXPENSIVE CELL FOR ELECTROLYSIS.

Dr. E. J. Buckmaster exhibited the cell, which consisted of a glass fruit-jar; a cover of six layers of pasteboard tacked together, with two perforations, one for the carbon, the other for the zinc plate; the zinc was six inches long, and pierced at one end; the exciting fluid, two or three ounces for each cell; wire for making the necessary attachment. If made at home it cost about twenty-five cents. An instrument for use by the gynecologist should possess the following characters: 1. The electro-motor force should be fairly constant. 2. It should not work on an open circuit. 3. It should be simple in mechanism, so that the operator could provide for any irregularity in its working. By employing two carbons his instrument would be found equal to almost any cell in use.

Dr. R. G. Wiener read the

REPORT OF A CASE OF PLACENTA PRÆVIA, WITH SPECIMEN.

The placenta was not lacerated on the side, but showed simply the rent through which the child was brought into the world. He had attended the woman in normal labor twice before. October 7th he was called and found her in bed, bleeding profusely. She had been pregnant about seven and a half months, and had felt quite well until seized with hemorrhage while at stool. The os was found closed, but the cervix felt boggy. He administered some morphine, tamponed; the hemorrhage ceased. He reintroduced a tampon twice daily for a week, during which time she had no hemorrhage. On the 17th she began to flow again, profusely. The os was somewhat dilated, the placenta adherent centrally. He could discover no presenting part of the child. The woman was etherized, and he tried to dilate the cervix with the finger and remove the placenta laterally, but failed. He then plunged through the placenta, and extracted the child by the feet after version. The woman was nearly exsanguinated, but the ether acted as a stimulant, and also caused vomiting, and thereby favored contraction of the uterus. The child and mother had done well since. He used ether in preference to chloroform for the reasons just suggested.

Dr. Malcolm McLean remarked that he had only one way of managing such cases, namely, to dilate the os, which he did with an india-rubber dilator of his own construction, then plunge through the placenta, if necessary, and deliver. Such a case would be a poor one in which to follow the method of Braxton Hicks, viz., to turn, bring down one leg, and wait for delivery.

Dr. Wiener stated that he did not wait at all after dilating.

Dr. J. R. Goffe then read the

REPORT OF A CASE OF HYSTERECTOMY FOR FIBROID TUMOR, WITH SPECIMEN.

He reported the case more especially to bring out the method of disposing of the pedicle. The patient was forty-one years of age, never pregnant. For six years she had had distress in the pelvis, more aggravated the past three years, but without hemorrhage. It being a multiple fibroid, Dr. Goffe advised an operation in preference to electrolysis. The tumor was firmly wedged in the pelvis, but he was finally enabled to throw an elastic ligature around it, dissected the bladder off its anterior face, pulled down the broad ligaments, transfixed the cervix, tied on either side as he would the pedicle of an ovarian tumor, using silk. He then used the bladder, which he had dissected off the face of the tumor, as a flap, carrying it over the stump as far down in Douglas' pouch as it would reach, laying it over smoothly and also so as to make pressure on the stump, sewing it across the back with catgut. He hoped to get primary union, but if not, there would be the cervix to fall back upon for drainage. After three or four days there was some elevation of the temperature. Suspecting suppuration under the flap, he dilated the cervix, when about an ounce of pus was made to escape. In order to keep the cervix open for drainage he inserted a tube employed by Peaslee for making applications to the interior of the uterus. By attaching a soft rubber tube to the rim of this the discharges were conducted outside the vulva. Through this the cavity was syringed out. The discharge continued six weeks, when it ceased entirely, and the patient had since remained well.

Dr. Goffe also presented a specimen of

PROBABLE ECTOPIC GESTATION AND PYOSALPINX,

removed that morning from a patient who had been under treatment by another physician during three months. A tumor on the left side of the uterus was removed, and contained pus, and was shown to be a pyosalpinx. From the right of the uterus a round mass the size of an orange was removed, and the inside contained what appeared to be a fœtus and placenta. A microscopic examination would be made to determine its character.

Discussion on the cases being invited, Dr. Goffe added that Dr. Emmet had informed him of having disposed of the stump in a similar way in hysterectomy some years ago, but he did not think to drain as Dr. Goffe had done; an abscess developed, and caused the patient's death.

Dr. A. P. Dudley spoke with fervor in behalf of treating the pedicle as Dr. Goffe had done. Each operator was likely to have a strong preference for some particular method, but he had tried the extraperitoneal method of treating the stump so highly recommended by Bantock, with much less favorable results than by dropping it. It was especially objectionable in causing the patient so much suffering during the healing process. As to covering the stump, five weeks ago he did this, stripped the external layer off the fibroid growth and around the uterus, ligated the stump with catgut, cut it short, then stitched the peritoneum or outer covering of the fibroid growth over the stump with catgut. On the fourth day there was a rise of temperature, and he dilated the cervix, but only sufficiently (the patient being a primipara) to introduce a soft-rubber drainage-tube, and conducted the pus which afterward formed beyond the vulvar outlet. She recovered.

The Chairman remarked that the tube used for drainage by Dr. Goffe was employed by Dr. Peaslee for making applications to the interior of the uterus as many as twenty years ago, and he had himself found it fulfil the purpose well. He suggested that in cases like Dr. Goffe's and Dr. Dudley's, if suppuration was expected, it might be well to introduce this tube during the operation and avoid the necessity for subsequent dilatation of the cervix. It could be readily withdrawn when danger of suppuration had passed.

SPECIMENS OF UTERINE APPENDAGES.

Dr. A. P. Dudley presented the specimens which had been removed that day in a case in which he had expected to do simply hysterorrhaphy for a displaced and adherent uterus, but the enlarged and diseased condition of the uterine appendages made it necessary to remove them. The specimens were of interest in showing so well the veil-like inflammatory products covering the tubes and ovaries, and adhesive bands which had extended to the rectum, and also a peculiar shape of one ovary, it being like that of a horseshoe. There was a uterine fibroid.

Dr. A. P. Dudley then read the paper of the evening.

A NEW METHOD OF OPERATION FOR RESTORATION OF LACERATED PERINEUM.

When the author entered the Woman's Hospital as interne, Dr. Emmet was employing his new operation for restoring the perineum. Dr. Dudley adopted the procedure, but since, after five years' experience, it continued to give unsatisfactory results, he concluded that it could not be founded on a correct anatomical and physiological basis. Aside from this fact, the operation was difficult to describe and hard for the general practitioner to perform. To devise a successful method of restoring the lacerated perineum required a thorough study of the anatomy of the parts. The text-books in general were very faulty in this regard. He knew of but one, that of Dr. Ranney, on the topographical relations of the female pelvic organs, published in 1883, which was at all satisfactory.

Two questions arose which should be settled before undertaking a new operation: (1) What is the structure of the tissues involved in laceration of the perineum during childbirth, and what are they designed by nature to do? (2) What is the true nature of the injury done the parts, and which is its most important element? Both of these were disputed questions, and according to the answer given would be the method of repair.

Dr. Emmet held that it was usually the pelvic fascia at the sulci which was torn away from the posterior vaginal wall.

Dr. Dudley thought there was no doubt this fascia was frequently injured, but that it was of secondary importance, the real damage consisting in the extent to which the perineum proper was lacerated. He presented diagrams showing the anatomy of the female perineum, which he described at length. On removing the skin and superficial fascia the first muscle seen was the transversus perinei, and just beneath it were two larger muscles, the constrictor vaginæ and erector clitoris. Between these and the levator ani (the most important muscle in the pelvic floor) were two layers of deep perineal fascia, dense fibro-elastic fascia stretching across the anterior half of the pelvic outlet. The levator ani constituted the diaphragmatic muscle of the pelvis. It was with the anterior and middle fibres of this muscle that we had to deal in ordinary cases of lacerated perineum.

It would be seen that there were three sets of muscles in the floor of the pelvis, each surrounded by distinct layers of fascia; that all took their origin from the inner walls of the pelvis, and converged to enter a tendinous centre in the median line of the perineum. It must be clear that if the central tendinous union were severed the opposing muscles would contract and leave a gap. The fascia covering these muscles was of a fibro-elastic nature, capable of stretching, but not of itself capable of contracting. Therefore when it was lacerated it changed its position only as the muscles changed their position. The most important of this fascia was the deep perineal, or tranverse, ligament, which served a threefold purpose, that of giving extra support to the muscles of the anterior half of the pelvic floor, of protecting and supporting the blood-vessels, and of acting through some of its elastic fibres, extending from the side of the pelvic outlet, like the string of a purse.

It was usual for the laceration to take place in an antero-posterior direction, and in such cases the floor of the pelvis gave way; but in some it was in a transverse direction, and here no prolapsus of the vagina or rectocele would result. When the laceration was in the second degree, according to the common classification, involving the entire perineal body down to the sphincter ani, the condition was much more serious than when only in the first degree. The central tendinous tissue being torn through the muscles contracted to either side, destroyed the support of the vagina and rectum, and the efforts at stool soon brought on rectocele, then followed prolapsus of the posterior wall of the vagina, then of the uterus and of the bladder. In order to thicken that portion of the perineal wall which had to resist the greatest strain during lifting and defecation, and to throw the rectocele back into the vagina, where it belonged, he began his operation by denuding a semicircular surface, exposing the muscular aponeurosis from the vaginal angle down to the hymen, and from here denuding a triangular portion to the central posterior vaginal wall, sometimes a distance of two inches. The surface denuded was somewhat like that in Martin's operation. The novel feature of his operation was more particularly the direction of introducing the suture, and it was this which thickened the posterior wall and restored the sphincter action of the perineum, and gave support to the parts above.

He employed catgut, made the suture continuous, and instead of introducing it in a direct line across the pared surface, or curved upward as was customary with operators, he curved it downward. When the operation was completed the line of sutures was in the centre of the perineum and posterior wall of the vagina. The puckering was on the under surface, leaving the line of suture outwardly smooth.

Dr. Goelet described an operation which he had been doing for lacerated perineum the past eight years, an account of which he published in the *Medical News* five years ago. This, he thought, was similar to the operation done by Dr. Dudley, but admitted his error, especially as to the direction of the suture, when he better understood the latter.

Dr. Malcolm McLean had been unable to obtain satisfactory results from Dr. Emmet's operation. He considered it essential to restore the raphe in the line of separation of the muscles of the perineum. For an hour or two after laceration the parts lay in their natural relation, but soon the muscles regained their tone and retracted.

Dr. A. F. Currier thought Dr. Dudley's elaborate argument would prove a credit to the transactions of the section. It seemed to him that any success in restoring fascia to fascia and muscle to muscle would prove largely imaginary. After the lapse of time such retraction and atrophy took place in the injured parts that he could not convince himself of his ability to restore them as they were originally arranged by nature. But he understood the principle which Dr. Dudley wished to carry out to be the introduction of the sutures in such a way as to cause the opposing parts to so counterbalance each other as to make a sufficiently resisting structure. With that view he coincided, and in so far as Dr. Emmet's last operation fell short in this respect, it was faulty. Nothing had been more impressed upon his mind the past year than the value of the perineum as a barrier to prolapsus of the vagina and uterus. There were other operations which he thought would prove as valuable as the one described by Dr. Dudley, for instance that of Martin. He had himself the last year or two done an operation somewhat like that of Dr. Dudley's, but perhaps less effective. The sutures were not directed as much downward.

Dr. J. R. Nilson thought the operation described by Dr. Dudley was a combination of that of Hegar's and another, except that the sutures were passed downward instead of directly through. It was his impression that Dr. Dudley's method of passing the sutures would not draw the tissues up, as he intended, but rather draw the softer vaginal tissues from above down. He had tried earnestly to follow Dr. Emmet's last method, but failing to get satisfactory results, was obliged to abandon it. He had found since adopting the method of burying the sutures that he obtained better results. Having drawn the two rows of buried sutures together, and feeling the tension becoming great, he put in two or three silk-worm sutures to give extra support during the operation.

Dr. Dudley said that all he claimed as absolutely novel about his operation was the manner of introducing the sutures. Heretofore operators had directed them either upward or across in a right line. After his operation patients had sphincter action, and were able to close the vagina.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting held Tuesday Evening, November 6th.

The President, Dr. George W. Jacoby, in the Chair.

Dr. W. H. Thomsen read a paper entitled,

PARENCHYMATOUS NEURITIS,

including the history of a number of cases.

Case I. was that of a man fifty-six years of age, formerly engaged in the lumber business and obliged to stand in water containing floating ice for hours at a time. This patient's symptoms had first pointed to central spinal trouble, but later had been those of a multiple neuritis. They had, however, been gradual in their onset and there had been no evidences of pressure. There had been no shooting nor lancinating pains. The actual cautery had been applied over the spine, and the hot glass-rod over the sensitive nerve-trunks. Nitro-glycerine had given the greatest relief from pain in this case.

Case II. was that of a man thirty-five years of age, convalescing from diphtheria. There was no pain, but the laryngeal and pharyngeal paralysis was so profound that the general health suffered.

Case III. was that of a boy convalescing from typhoid fever. There were pains in the legs and feet with dropping of the feet.

Case IV. was that of a woman confined to her bed for three months in the course of phthisis. There were pains in this case in the feet extending to the knees, and in the hands with drooping of the ankles and wrists, which progressed steadily till death, when extensive nerve degeneration was found without any evidences of inflammatory action. The case was presented as a typical example of a wide-spread non-inflammatory degeneration of the nerves. It was a parenchymatous neuritis analogous to that which could be produced by a ligature. The origin and history differed from that of an inflammatory neuritis, however much it might resemble this condition in its ultimate results. In the case of typhoid fever and phthisis the degeneration may have been due to a mechanical cause—pressure from the loss of the surrounding fat. The fact that the vagus was implicated in the latter disease did not disprove the theory, as no statement had been advanced in regard to the condition of the bronchial glands.

The theory of a non-inflammatory parenchymatous nerve degeneration was important, as the treatment of such cases would differ from that of cases of inflammatory origin. In the latter antiphlogistic and soothing treatment was indicated, while in the former stimulating applications were required.

It was questionable whether the term neuritis could be correctly applied to this type of the disease.

Dr. L. C. Gray had not heard the commencement of the paper, and did not understand why Dr. Thomsen objected to the term neuritis. He thought that the symptoms could be scarcely classed under any other name. There had been, as he understood, downright pain in the course of the nerves, and eventually paralysis and atrophy. These were the clinical symptoms of neuritis, and measured the severity of the neuritic lesion.

The treatment of neuritis was, he believed, excepting traumatic neuritis, still *sub judice*. Since attention had been called to the disease all had probably met with cases in which no local measures seemed to do any good. Quinine, the salicylates, and iron had been most beneficial in his own cases. Change of air was to be recommended. Even in the paralytic stage it was his custom to move the patient to another part of the city, or even from a lower floor to a higher floor in the house. Change of location was especially indicated in the cases arising in our somewhat malarial suburbs.

Dr. Starr applied powdered menthol diluted with starch under a flannel bandage for the relief of the pains of neuritis.

Dr. Jacoby did not find the diagnosis of neuritis so easy as Dr. Thomsen had represented it, especially in typhoid fever. Myositis was a more probable lesion in typhoid fever. Zenker had even stated that neuritis was never found in this disease. As to the distinction made between the inflammatory and degenerative process, both might be found in the same case. Which process was primary and which secondary was still a question.

Dr. Thomsen closed the discussion. He had intended to call attention to only a single point and necessarily had neglected many others touched upon by the gentlemen in the discussion. He had intended to call attention simply to the impropriety of the term neuritis as applied to the process in the cases which he had described. There was no reason to suppose that the process in the case of phthisis had been inflammatory. The inflammatory process had certain definite characteristics. These were vascular disturbances, infiltration with serum and leucocytes or living matter. In the neuritis of alcoholism, both in private and in hospital practice, he had observed circulatory and nutritive changes, and there had been the same tendency as in the inflammatory processes in other parts of the body. There was evidently inflammation of the sheath of Schwann and constriction of the nerve. These conditions contrasted with those in the cases which he had described. In the treatment of true neuritis he had used an application of equal parts of the oil of peppermint and olive oil, a preparation similar in action to that which Dr. Starr had recommended.

Dr. Gray inquired whether Dr. Thomsen recognized no inflammatory process within the sheath of Schwann.

Dr. Thomsen replied that he knew of no changes within the sheath of Schwann which could be called inflammatory.

Hypodermic Medications.—The following precautions are worth remembering: Solutions of the alkaloids soon decompose and should therefore be freshly prepared. The smallest size of each tabloid given is the one generally preferred. The dose, hypodermically, is always less (the proportion varies) than by the stomach Great care should be taken not to throw a medicament into a vein, and so produce a sudden overwhelming effect. Fatal collapse might ensue from injecting air into a vein. Absorption of an injection over the temple or chest is twice as rapid as elsewhere. The prick of the hypodermic needle in the chest has been followed by instant death. Syncope may follow an injection, if the patient do not remain quiet and lying down. For safety and freedom from pain, an injection should be made in the outside of the arms or thighs, or in the abdomen or back. Injections should not be made over bony prominences, or into inflamed or tense tissues. Mercury, ergot, etc., are best injected into the muscles, as in the nates. It is not usually considered safe to repeat an injection (as of morphine) for twenty or thirty minutes.—*Hospital Gazette.*

Small-pox in France and England.—In the last annual report of the "Bureau de l'Hygiène Publique" a comparison is made, in regard to the mortality from small-pox, between France and England, much to the disparagement of the former. In the larger cities of France the number of deaths from small-pox, during the year 1887, was 1,956, or 0.31 per thousand of the living population. In the larger cities of England, during the same period, the number of deaths was 332, or 0.04 per thousand of the living population. Thus the fatality from small-pox was nearly eight times greater in France than in England. Vaccination is compulsory in England.

OUR PARIS LETTER.

(From our Own Correspondent.)

THE PASTEUR INSTITUTE—INTRAVENOUS INOCULATION OF RABIC POISON—ANOTHER STUDY OF TETANUS; IS IT INOCULABLE?

Paris, November 23, 1888.

The new Pasteur Institute, of which I gave a brief description in The Medical Record of October 28th, was opened on Wednesday, November 14th, in the presence of a large assembly, presided over by the President of the Republic. Several distinguished persons were also present, represented by some of the ministers, the presidents of the two Chambers, and a large number of members of the Institute; but it may be remarked that neither the Academy of Sciences nor the Academy of Medicine was officially represented at the ceremony, and the Municipal Council of Paris was conspicuous by its absence. The proceedings were opened by M. Bertrand, Permanent Secretary of the Academy of Sciences, who made a eulogistic speech on M. Pasteur and his numerous scientific researches. Dr. Grancher, M. Pasteur's principal assistant, then read a report of the work done in antirabic inoculations since the middle of 1885, when the first two human beings were inoculated. He stated that the number of persons treated at Paris in the Rue d'Ulm and the Rue Vauquelin during the years 1886-1887 to July 31, 1888, was 5,384. The rate of mortality had been 1.34 per cent. for 1886, for 1887 it was 1.12, and for 1888 it was 0.77 per cent. This rate of mortality comprises the deaths of persons who were affected with rabies the day after inoculation; but, remarked Dr. Grancher, even these figures are very striking, as the estimated mortality previous to the discovery of this method of treatment was 15.90 per cent. as given by the Reporter of the Council of Hygiene of Paris. Dr. Grancher informed his hearers that twenty laboratories for antirabic inoculations have been established in different parts of the world: Seven in Russia, five in Italy, and one each in Roumania, Austria, Brazil, Cuba, and the Argentine Republic, while two more will shortly be opened at Chicago and Malta. The staff of the new Institute are disposed of as follows: Dr. Grancher, with the assistance of Drs. Chantemesse, Charrin, and Terrillon, will attend to the department of the treatment of rabies. M. Duclaux, one of M. Pasteur's most ancient pupils and now Professor of Biological Chemistry at the Faculty of Sciences, will direct the laboratory of general microbiology. M. Chamberland is charged with microbiology in its relations with hygiene. Dr. Roux will teach the microbian methods in their applications to medicine. Drs. Metchnikoff and Gamaleia, of Russia, will study the morphology of inferior organisms and comparative microbia. The new Institute will thus, as expressed by M. Pasteur, serve as a dispensary for the treatment of rabies, and will at the same time constitute a centre of researches for infectious maladies as well as a centre of instruction for the study of microbiology, and will be open to medical men of all nationalities.

M. Chauveau, Professor of Veterinary Medicine, recently read a paper at the Academy of Sciences, on behalf of M. Galtier, on certain experiments tending to demonstrate the efficacy of the intravenous injections with rabic virus in view of preserving from rabies animals bitten by rabid dogs. After having, since 1880, established, by experiments on the sheep and the goat, that immunity against rabies, by means of these injections, M. Galtier has, in recent communications, demonstrated that, by this means, herbivorous animals may be preserved, even after the lapse of a certain time after the bite. These results have been fully confirmed by recent experiments of MM. Nocard and Roux. The method is applicable to ruminating animals and to pigs; it presents no serious difficulty in its application. The matter to be inoculated may be taken from the dog which had inflicted the bite, and it is sufficient, to obtain it, to dissolve in water the nervous substance, then to decant it after sufficient rest, or to filter it, to remove the solid particles which might cause accidents in the blood-vessels. The injection may be practised without having any mental preoccupation about the contamination of the perivenous tissue, for, even should the latter be contaminated, the success of the operation is none the less sure. By still more recent experience, M. Galtier has been led to conclude that one can with certainty preserve, by means of these intravenous injections, herbivorous and omnivorous animals which had been bitten by mad dogs. It is, moreover, permitted to presume that the immunity conferred has for effect not only to preserve against the consequences of bites already received but that it also guarantees against ulterior bites.

The subject of tetanus every now and then surges up at the Academy of Medicine, and a commission has been formed to investigate its true nature, of which Professor Verneuil, so well known in connection with this subject, has been appointed permanent Reporter. Dr. Alphonse Guerin, who, it will be remembered, was the first who had the idea of sheltering wounds against the germs of the air, to carry out which he invented the cotton-wool dressing which bears his name—like M. Verneuil, M. Guérin thinks that tetanus is inoculable, transmissible, and that there cannot be any contestation on this first point, which is very important. It is therefore certain that there is a virus in tetanus; but, adds M. Guérin, one does not know exactly what this virus is. According to some authors it is a microbe; but, if this be the case, one should be able, in protecting wounds against the contact of the air, to prevent the production of tetanus in the same way that one can, by this means, prevent purulent infection, erysipelas, etc. This, however, is not the case, as, M. Guérin observes, tetanus frequently occurs even under the cotton-wool dressing. Another objection against the microbian nature of the malady is that the antiseptics—Lister's dressing—do not prevent the production of tetanus. Therefore, if it were due to a microbe, all the antiseptic theory would be completely overthrown. This is why M. Guérin considers as much more probable the intervention of a poison analogous to strychnine, or to that of a ptomaine or a poison manufactured by the organism. This poison is localized in the spinal marrow and there produces a partial acute inflammation, with ramollissement, which, M. Guerin says, he had frequently met with at necropsies.

ORGANIC UNION OF THE MEDICAL SCHOOLS AND UNIVERSITIES.

To the Editor of The Medical Record.

SIR: The editorial notice, in THE MEDICAL RECORD for October 13th, of Professor Welch's address on the above subject recalls to mind a paper read by myself before the Westchester County Medical Society in the spring of 1887. The paper was mostly taken up with a discussion of preliminary medical education. After an examination of the claims of various branches of study and their relative merits in a scheme of general as well as special education, the following course was suggested, it being understood that the student had already taken the usual course preparatory to entering college, Greek only being omitted:

"First year—Latin, Algebra, and Geometry, Elementary Chemistry, with lectures once or twice per week in History or English Literature. Second year—French, Trigonometry, Mechanics, and Optics, Analytical Chemistry, and lectures as in first year. Third year—French finished, German begun, Physiological Chemistry, Anatomy, and lectures on Logic. Fourth year—German, Physiology, Materia Medica, and Theory and Practice of Medicine. At the close of this year the student to be admitted ad gradum Med. et A.B. The fifth year should be given to lectures on Obstetrics and Surgery, and clinical lectures in all departments, together with study of the microscope and instruments of diagnosis, leading to the degrees of A.M. and M.D."

In the course outlined it was contemplated that the four years' study leading to the degree of Med. et A.B. should be pursued in some university, while the last year, leading to the degrees of A.M. and M.D., should be taken in the hospitals and a medical school of a large city. The A.M. to be conferred by the university and the M.D. by the medical school. If in addition to this the candidates should be required to pass an examination before an impartial board, in no way connected with any medical school, in order to obtain a license to practise, the profession and public would be reasonably well protected against the turning loose of half qualified or wholly unqualified practitioners to prey upon the community.

One of the incidental advantages which might accrue, in case some such system should be generally adopted, would be the effect upon the legions of supernumerary schools whose only *raison d'être* is the advertisement of their faculties. These *might* quietly efface themselves lest they be ground to powder between the nether millstone of the university and the upper millstone of the great clinical school. Another advantage is the partial separation of the theoretical from the clinical courses. Clinical advantages are simply wasted upon the student who is just beginning his foundation studies in anatomy, physiology, and chemistry. Much better that he should be at the same time attending to his general culture and broadening his mind in the atmosphere of the university, taking advantage of all of its privileges. When the foundation is properly laid he is ready to profit by the clinical wealth of our large cities, where the clinical lectures illustrate the didactic, and the didactic explain the clinical; these being further supplemented by studies in the dissecting-room and dead-house, and in the use of the microscope and various instruments of diagnosis. Coming to his practical studies with such a foundation as would be laid in the first four years, the student would accomplish more in one year than he could do in three years starting with the preparation of the average medical student. On the other hand, the five years' course, compared with the usual college course with the three years' medical course added, would be attended with a saving of two years while giving at least as good, probably better, results.

This course is not offered as being ideally complete either from a literary or professional point of view, but it is sufficiently complete for practical purposes, and the gaps may be filled up in that time of leisure before referred to (the time between hanging out the shingle and getting fairly into business); for the student who has faithfully pursued this course has become a master in the art of study, and henceforth is capable of both choosing and directing his own studies; and this after all is the main consideration.

J. H. CHURCHILL, M.D.

"CIRCUMCISION BY MATERNAL IMPRESSION."

To the Editor of The Medical Record.

SIR: In THE MEDICAL RECORD, page 535, November 3, 1888, Dr. J. G. Harvey relates a phenomenon which, if accurately reported, should receive attention sufficient from the profession to establish the fact beyond question.

Suffice it that most physicians will deem a mere statement of a phenomenon so much at variance with the best scientific conclusions worthy of credence only on indisputable evidence.

The points at issue are somewhat as follows: According to Dr. Harvey, the malformation must have taken place about the fortieth day of intra-uterine life.

At that period in gestation the fœtus "is a minute, gelatinous, and semi-transparent mass," about one *line* and one-half in length—we might say, "without form and void."

That circumcision could have taken place from any physical or muscular action seems scarcely a scientific or possible view. A surgical operation posited in so minute a protoplastic mass is an absurdity.

Further, science does not yet account for intra-uterine malformations by "maternal impressions" of this character.

Obstructions of circulation that arrest normal development of the fœtus cover most cases. The rest are accounted for by an abnormal condition of the generative material in one or both parents.

It is very true that the mental emotions of the mother may obstruct the circulation, but the action is upon the whole system of the mother and fœtus, and not through the blood upon a particular organ of the fœtus.

To hold any such doctrine as specific impression would jeopardize every child born into the world. Malformations and monstrosities would be in the majority and subject to the caprice of the parent.

It is scarcely necessary for the medical profession to countenance the fading superstition of "maternal impression," kept alive by tradition and gossip, and made a source of mental anxiety to many pregnant women.

Until there is stronger proof and more uniformity of results, is it not the office of the true physician to relieve our prospective mothers of a tension of mind most productive of the very disorders we so much deprecate?

M. G. Lowrey, M.D.

Boulder, Col., November 15, 1888.

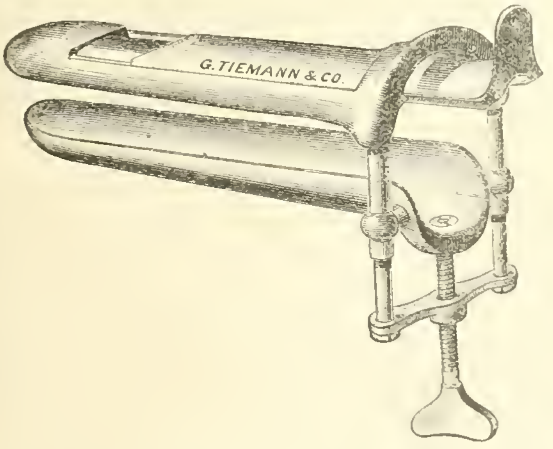
New Instruments.

AN IMPROVED RECTAL SPECULUM.

By J. B. POUNCEY, M.D.,

BIRMINGHAM, ALA.

The points of superiority are: 1st. The instrument, as shown in the cut, has two blades, the lower blade fitting into the upper, making it small and compact. 2d. The facility and ease of introducing. 3d. After the introduction of the instrument the rectum can be dilated to any desired extent by running up the screw attached to the blades. 4th. If this is done, any tumors, fistulous tracts, ulcers, etc., are in plain view for treatment. 5th. The blades dilate equally at both the internal and external openings. 6th. There is a wide slot in the upper blade, covered by a slide, which, when withdrawn, exposes the diseased parts fully to view.



"A Possible Revolution in Medicine" is the title of an article in *The Forum*, by Dr. Austin Flint. The author takes a very roseate view of the possibilities of medicine through the aid of bacteriology.

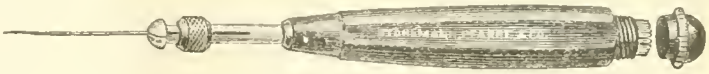
A NEW VACCINATOR.

By CYRUS EDSON, M.D.,

NEW YORK.

The little instrument shown in the cut has been in the hands of members of the vaccinating corps of the Health Department during the past year, and has proved very useful. It consists of a needle-holder, similar to those used by microscopists, having two jaws that are approximated by means of a sliding ring. These jaws are funnel-shaped at their extremity in order to facilitate the introduction of the needle, which is inserted to the depth of three-fourths of its length.

The handle is of hard rubber, with hollow space sufficiently large to hold twenty-five No. 5 needles. To use the instrument the operator unscrews the cap, selects a needle, fixes it in the jaws, and proceeds to scarify. Having performed the operation, the needle is removed and thrown away.



The scarification made by the needle will be found to be better for the purpose in question than that made by the lancet—the skin and vessels being torn, and not cleanly cut. The result is that a larger absorbing surface is exposed and just sufficient blood and serum exuded to dissolve the virus from the quill.

The instrument can be used more rapidly than the lancet, if time is taken to cleanse the latter after each vaccination is performed.

The cost of needles is only five or six cents per paper of twenty-five.

The device was contrived partly to meet the objections to vaccination made by parents of children attending school, on the ground that in the use of the lancet disease was liable to be transmitted from child to child. Indeed, one case of skin disease was alleged to have been caused in this manner; investigation, however, disproved it.

The popular prejudice against the lancet is deeply rooted and is best and easiest overcome by the new vaccinator. It is manufactured by Stohlmann, Pfarre & Co.

Health Department, City of New York.
November 19, 1888.

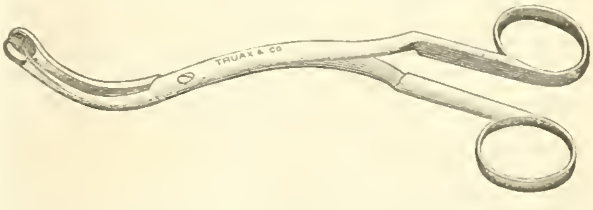
POST-NASAL PUNCH FORCEPS.

By MOREAU ROBERTS BROWN, M.D.,

PROFESSOR OF LARYNGOLOGY AT THE CHICAGO (ILL.) POLICLINIC.

The accompanying cut illustrates a pair of punch forceps which I have used for the past two years to remove adenoid growths from the naso-pharynx.

The advantages claimed for the instrument are, ease of introduction into, and ability to reach, any portion of the post-nasal space, while elevated growths only can be seized and these readily removed by being cut entirely through. The blades are one and a half inch long, and at an angle of fifty degrees (not so appearing in the figure) with the body of the instrument; one terminates in a ring-shaped knife, the other is solid, with a flat, soft, copper-faced surface.



The upper part of the blades will not separate, however firm the handles may be pressed toward one another.

It was suggested to me by Mr. Haussman, the maker of the original instrument, that the solid blade be also made a ring; but not being satisfied with other forceps so constructed, that I had used, I preferred them as here described. Messrs. Truax & Co., of this city, are now making them according to both patterns.

126 State Street, Chicago, Ill.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department. United States Army, from December 2, 1888, to December 8, 1888.

Williams, John W., Major and Surgeon. Is hereby relieved from further duty with the battalion of the Second Artillery at Fort Wadsworth, New York Harbor, and will proceed to join his permanent station, Jackson Barracks, La. Par. 3, S. O. 256, Headquarters Division of the Atlantic, Governor's Island, New York City, December 5, 1888.

Ball, Robert R., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War the leave of absence granted in Special Orders No. 129, October 18, 1888, Department of the Missouri, is extended one month. Par. 11, S. O. 279, A. G. O., Washington, November 30, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 8, 1888.

Bransford, J. F., Surgeon. Detached from Smithsonian Institution and granted six months' leave, with permission to go abroad.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 8, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	23	9
Scarlet fever	158	26
Cerebro-spinal meningitis	0	0
Measles	299	21
Diphtheria	140	35
Small-pox	1	0
Yellow fever	0	0
Cholera	0	0

The Late Dr. Henry B. Sands.—At a special meeting of the Medical Board of "The Roosevelt Hospital," held on Tuesday, November 20, 1888, the following entry was made in the minutes:

(Signed) J. West Roosevelt,
Secretary.

"The death of Dr. Henry B. Sands removes from among us one who, as Chief Surgeon of this Hospital, not only faithfully performed every duty but elevated the character of the whole institution.

"An Attending Surgeon to the Hospital from the date of its opening, November 2, 1871, his time and his great talents were freely given to its service. Careful and thorough in his work, skilful as an operator, clear and accurate in his judgment, truly and unselfishly considerate of the patients committed to his charge—his resignation upon March 31, 1888, was a most serious loss. Yet so thorough had been his work, so complete his method of organization, that his influence has remained a permanent good.

"On May 30, 1882, he was appointed the sole Attending Surgeon to the Hospital. He had long advocated the plan of organization with a single responsible head to each department, a plan till then untried in any large hospital in the United States. His strength of purpose and determination overcame all obstacles. This appointment was a great compliment to his professional reputation and personal character, and he showed himself worthy of the trust reposed in him.

"Such was his energy and such his devotion to work that he left the hospital with a surgical department second to none in the country. The chief ambition of his professional life was realized, and he had the satisfaction of seeing the system, for which he had done so much, firmly established.

"The Members of the Medical Board inscribe in their minutes their high appreciation of the services rendered to the hospital by Dr. Sands; their recognition of his extraordinary ability; and their deep sorrow for the loss to themselves and the entire community of so great a surgeon and so good a man."

A New Operation for Syndactylism.—Dr. E. Engdahl, writing in *Hygeia* for October, 1888, proposes a new operation for the correction of syndactylism. He makes longitudinal incisions along the palmar surface of the united fingers, starting from just above the metacarpophalangeal articulation and terminating at the end of the connecting web. A transverse incision at the extremity of the web connects these two, care being taken to divide the integument only. The strip so formed is dissected back. Then the dorsal surface of the connecting web is divided between the fingers. The palmar flap is now turned over so as to form a commissure between the fingers, and is stitched to the dorsum. The raw surfaces at the sides of the fingers are allowed to heal by granulation, being kept from coming in contact by pledgets of lint. The author has used this method in two cases, one of congenital syndactylism, the other resulting from a burn, and with complete success.

"La Gazette Médicale de Liège," is a new medical journal, published at Liege, the first number of which appeared in October. The journal will appear weekly, and is under the editorial management of Dr. Brasseur.

Empedocles as a Bacteriologist.—The favorite theory of Empedocles, the famous philosopher of Agrigentum, was that the blood of man contained an infinite number of demons. Now, allowing for the state of medical science in the period at which Empedocles lived, we must not be too severe upon him; less so, because at the present day we have a revival of his theory, with this slight difference, that the microbe has taken the place of the demon.—*The Provincial Medical Journal.*

Why Albinos do not See Well.—According to Dr. A. D. Williams the white flaxen hair of albinos shows that there is a deficiency of coloring material in their bodies. Further proof of this fact is found in the absence of the necessary amount of pigment in their eyes. Such persons have pink eyes because there is not pigment enough in the iris and upon its posterior surface to prevent the red reflex of the fundus from shining through the iris. Such persons are always greatly annoyed by strong light, because there is not sufficient color to prevent the ingress of a flood of it. It enters not only through the pupil, but through the substance of the iris as well. The choroid being likewise deficient in pigment, the excessive amount of light dazzles and greatly confuses vision. Furthermore, the deficiency of pigment in the choroid prevents the light, after it has properly acted on the retina, from being absorbed, that being the main function of the choroidal pigment. Albinism is an unfortunate condition, as there is no way to supply the deficient pigment to the iris and choroid. The annoyance is somewhat palliated by the use of properly-colored glasses. These supply the place of the natural pigment to a slight extent.—*St. Louis Medical and Surgical Journal.*

Original Articles.

A CONTRIBUTION TO THE TREATMENT OF FRACTURES AT THE LOWER END OF THE HUMERUS, BASED ON THE ANALYSIS OF FIFTY CONSECUTIVE CASES.[1]

By CHARLES A. POWERS, M.D.,

SURGEON TO THE OUT-PATIENT DEPARTMENT, CHAMBERS STREET HOSPITAL, NEW YORK.

Among the minor injuries which fall to the care of the general practitioner there are, perhaps, none which give him more concern than this to which your attention is invited. And I venture to say that few experienced surgeons undertake the treatment of one of these fractures without confessing to themselves a decided doubt as to whether the result in the given case is to be all that they can desire.

The importance of the theme, then, rather than the presentation of new methods of treatment, must be my apology for bringing it before you.

I will not occupy your time with a literary history of the subject, but briefly place before you an accurate picture of the cases which have been under my care in the out-patient department of the Chambers Street Hospital during the past eighteen months.

These have been fifty-six in number, six of which passed from observation shortly after they were hurt and which are excluded from the list, leaving fifty cases, classified as follows: Ten of the internal epicondyle; 12 of the internal condyle entering the joint-surface; 15 of the external condyle; 6 through the base of the condyles; 2 through the transverse epiphyseal line; 4 T-shaped or comminuted; 1 separation of the trochlear epiphysis. Nine of the patients were over twenty years of age, and 41 were under. Of the 41, 13 were under five; 12, between five and ten; 13, between ten and fifteen; 3, between fifteen and twenty. The age of the youngest was two years; that of the oldest, forty-three. Forty were in males, ten in females; forty-nine were simple fractures, one was compound.

Class A. *Fractures of the internal epicondyle.*—Of this lesion there were ten cases, of which the following is a fair illustration: P. B——, a boy, eight years of age, fell three feet, striking on the inner aspect of the left elbow, some half-hour before applying at the hospital. Examination revealed tenderness over the inner condyle, together with moderate swelling. Active movements at the elbow were feeble and painful. The internal epicondyle was freely movable, and on moving it crepitus was elicited. In full extension of the forearm it slipped a little downward, but on flexing the elbow to a right angle it was easily replaced.

The forearm was placed, midway between pronation and supination, at an angle of ninety degrees with the arm, and a plaster-of-Paris splint applied with equable, moderate pressure from the wrist to the upper third of the arm. This splint gave rise to no inconvenience, and was left in place ten days, at the expiration of which time it was removed and the joint inspected. The swelling had nearly disappeared and there were no untoward evidences. A fresh plaster splint was applied, and left in place until the twenty-eighth day, when it was removed. Firm union was now found to obtain. The joint was free from pain and swelling. The epicondyle was in place, moderately thickened.

The patient could flex the forearm to seventy-five degrees, and could extend it to one hundred and thirty-five degrees. Pronation and supination were nearly perfect. The parents were directed to bathe the elbow morning and night in water as warm as he could comfortably use, to follow the bath with inunction of neat's-foot oil, and to apply a large flaxseed poultice when he went to bed, removing it in the morning. They were advised to confine his opposite arm to the side, beneath the clothing, and thus force him to use the affected limb in eating, playing, and his other daily habits.

The functions quickly improved, and on the sixtieth day they were completely restored. You will see that the elbow is now like its fellow, except for the moderate thickening which still persists at the seat of the fracture.[1]

Of the 10 cases—8 in children and 2 in adults—9 regained the functions perfectly; the other was lost sight of at the end of the second month, but at that time motions were nearly complete. In none was there resulting deformity, nor should we expect it in this class of cases, despite the assertion of Gross,[2] who says of fracture through the internal epicondyle: "Few cases recover without a certain degree of deformity, or even anchylosis." I know of no reason why there should be either, unless, perchance, the forearm flexors draw the fragment so far down that even complete flexion fails to permit its replacement.

I cannot insist too strongly on the importance of careful and systematic employment of the emollient measures, together with active motion after removal of the splint. On its removal the average range of motion found was thirty-five degrees, and this generally improved in direct proportion to the intelligence and faithfulness with which the patient followed directions.

Class B. *Fractures through the internal condyles entering the joint*—Twelve cases, of which the following may serve as an example:

T. D——, a boy, nine years of age, fell forcibly on the sidewalk, striking on the left elbow. Examination revealed all evidences of fracture through the humeral trochlea. There was a tendency to posterior displacement of the condyle, but when the forearm was in extension it made the normal angle with the arm. The elbow was placed at ninety degrees, midway between pronation and supination, and the condyle drawn a little forward to correct its displacement. Plaster splint was applied, and left in place twelve days; then removed; the condition found good and the splint reapplied. The second dressing was left on until the twenty-eighth day, at which time it was taken off and the following condition noted:

The elbow was painless, and but slightly enlarged; range of motion from eighty to one hundred and fifteen degrees; pronation and supination all but perfect; no apparent deformity. (It is well known that one cannot accurately judge of deformity at the elbow when the joint is flexed. It is only when in a nearly extended position that we can assure ourselves as to its presence or absence.) He was given the general directions as to massage, etc., and rapidly regained the functions. On the thirty-sixth day he could flex to sixty degrees, and extend to one hundred and thirty-five degrees. On the forty-second day flexion was perfect, and extension was to one hundred and fifty-seven degrees, while at the end of the third month the functions were completely restored. There was moderate thickening at the site of the fracture, but no real deformity.

---

[1] Read before the Surgical Section of the New York Academy of Medicine, May 14, 1888.

[1] Twelve cases, illustrating the various classes, were exhibited before the Section.

[2] System of Surgery, vol. i., p. 979.

That this form of treatment—confinement for four or five weeks without passive motion—is adapted to cases occurring in adults as well as in children is shown by this man,[1] forty-two years of age, who suffered a fracture through the internal condyle some fifteen months ago. It was accompanied by all of the usual evidences, and he was treated as were the cases whose histories I have just related. The splint was removed for good on the thirtieth day, at which time there obtained flexion to eighty degrees, with extension to one hundred and fifteen degrees. On the sixty-fifth day he had so far improved that he could flex to fifty degrees and extend to one hundred and fifty degrees. The functions are now all complete except extension. which is five degrees short.

When this man first applied for treatment his joint was the seat of extreme swelling, and it is especially in these cases that I have found the plaster splint most admirable. I know of no dressing under which the effusion will so rapidly subside. It exerts an equable pressure and it keeps the parts absolutely at rest. It remains where it is placed. I apply it to all cases as soon as seen. If the injury is very recent and one expects further swelling, especially if he has subjected the joint to much of manipulation in arriving at his diagnosis, he naturally applies the splint rather more loosely. And I know of no dressing which affords the patients as much of comfort as this; they very rarely experience pain after the first twelve or twenty-four hours. And in but one case has the splint required removal; this was in a child who had a T-fracture. The dressing was put on rather too tightly and had to be taken off the following day; it had occasioned considerable swelling of the hand.

These cases went through a prolonged examination before a permanent dressing was put on. Most of them, before reaching me, were examined by the surgeon in charge of another class and by one or two of his assistants. After applying to me they were subjected to further handling by my assistant and myself. I do not know that any of them were the worse for this manipulation, and it assures me that diagnosis was as accurate as possible; for if we failed to agree in diagnosis the patient was given an anæsthetic, and we then conferred until we did agree.

To recapitulate the twelve cases of internal condyle: Nine perfectly recovered their functions; in one all motions became complete except extension, this being five degrees short; one is *said*[2] to be perfect, though he has not been seen, and one is yet under treatment. In none is there deformity; one cannot consider the normal callous thickening which follows any fracture as true deformity.

CLASS C. *Fractures through the external condyle entering the articular surface.*—These may run from the outer border downward and inward to the capitellum, or farther in, reaching the trochlea. It is, however, most difficult to determine just the extent of the line, especially if there be much of swelling, and I have been content with putting them in one general class. Extra-articular fracture in this region I have not seen.

The general treatment has been as in the preceding classes. Of late, when first seen, the forearm has been placed in extension, and its angle with the arm compared with that of the opposite side; if no difference be noted, the elbow is incased in plaster at the angle of ninety degrees, but if there be a loss of the "carrying point" it is abducted to its proper position and put up at about one hundred and thirty-five degrees for a couple of weeks, at the end of which time it is brought up to the right angle.

CASE.—S. M——, a boy, five years of age, applied at the hospital, August 11, 1887, with a history of having fallen on the left elbow twenty-four hours previously. The distance of his fall was not known. He was found to have a fracture of the external condyle extending to the trochlear surface, with all regular evidences and slight posterior displacement. It was reduced, and put up in plaster at a right angle. Examined on the tenth day, and position found to be excellent. Splint taken off on the twenty-second day, at which time there was union with thickening and broadening of the condyles; flexion to eighty degrees, extension to one hundred and thirty degrees, pronation and supination all but perfect. General advice. On the twenty-sixth day (this was four days later) there was flexion to seventy-five degrees, extension to one hundred and fifty degrees. On the fortieth day flexion was perfect; extension, a few degrees short. Now all motions are complete, but you find the forearm more nearly in a straight line with the arm than on the opposite side.

I show you also a boy who was injured on May 13, 1887, just one year ago. He was treated in the same way, but did not escape deformity. The external condyle is very prominent externally and a trifle displaced backward. It simulates the "gunstock" deformity, yet, if you carefully compare the inner contour of the extended limb with that on the opposite side, you will see that there is no difference. The deformity is due to bony prominence, not to a changed axis of the forearm.

The results in these 15 cases of external condyle are not all that I could desire. I have noted 8 of them as perfect both in position and functions; 2 present no deformity, but the functions are a little short of complete; 2 have perfect functions, but a moderate degree of deformity; in 2 there is both deformity and limited motion, the latter, however, amounting to but a few degrees; 1 case is yet under treatment.[1] I have no doubt that in each the function will be completely restored, as its limitation does not in any case seem to be mechanical.

In each case the deformity is due to a marked prominence of the condyle and its slight backward displacement; in none is there a reversal of the normal elbow obliquity—the "gunstock" deformity.

CLASS D. *Fracture through the base of the condyle.*—Six cases—4 in children, 2 in adults; 3 were transverse, 3 oblique, the line of fracture in the latter running from a point somewhat above the internal condyle downward and outward to the external condyle. In all, the lower fragment was strongly drawn backward, occasioning the classic similarity to a posteriorly dislocated forearm. All were put up at a right angle, the forearm, which controls the lower fragment, strongly drawn forward until the epicondyles very fully regained their relation to the long axis of the shaft. Of the transverse fractures two recovered perfectly, and the other is, as you see, in perfect condition except that complete flexion is short, this being prevented by the coronoid process impinging on a considerable anterior callus. The oblique fractures occasioned more of trouble; one, in a child, resulted in extreme gunstock deformity.

CASE.—M. C——, a girl, aged three, injury not known; very much of swelling; lower fragment strongly drawn up. Placed at right angle, thinking that the deformity was well corrected, and plaster splint applied. The parents did not return with her until the thirty-ninth day, when the splint was removed. The external condyle was found to be very prominent, with bony fulness at the flexure of the elbow. Motion from eighty degrees to one hundred and ten. Six weeks later she had regained the complete use of the joint, with the exception of extreme flexion. The lower fragment was displaced upward and inward, and there was marked gunstock deformity. Had the patient returned as directed, the splint would have been removed at the end of ten days or two weeks, when deformity could, I think, have been corrected. In support of this I will ask you to contrast the following case :

---

[1] Patient exhibited.

[2] I have since examined this patient and found the joint free from deformity and the functions completely restored.

[1] This patient has since been discharged, with a perfect result.

B. C——, a man, aged twenty-nine, fell, three hours before his admission to the hospital, a distance of six feet, striking on the postero-external aspect of the left elbow. Oblique fracture through the condylar base, the lower fragment being strongly drawn backward, upward, and inward. The deformity was thought to be reduced, and the elbow put up at an angle a little greater than that of a square. The splint was removed on the fourteenth day, and the fragment found to have slipped a little inward. The forearm was now abducted to correct the deformity, and fixed at an angle of one hundred and thirty degrees. Splint removed on thirty-second day ; union ; motion through an arc of fifty degrees. Six weeks later the functions were fully restored. I show him to you now ; you see that there is much thickening, but no true deformity, the extended elbow having practically the same obliquity as its fellow.

These oblique fractures did not enter the joint, for the external condyle moved with the lower fragment.

CLASS E. *Separation of the lower epiphysis.*—Two children, one two and the other six years of age, presented themselves with this lesion, and in each a perfect result was attained by simple confinement at a right angle, the lower fragment being drawn well forward as in the fractures through the base.

CLASS F. *Comminuted fractures*—Four cases, of which the following are brief histories :

CASE I.—M. G——, three and a half years of age, girl ; one-half hour before admission slipped to the floor from a bed, striking on the right elbow. T-shaped fracture, with all of its evidences. Plaster splint applied at once, but it was put on rather tightly, and swelling necessitated its reapplication the following day. On the twenty-fifth day there was union ; functions, ninety and one hundred and fifteen degrees ; elbow much thickened. The functions gradually returned, and are now complete. There is no deformity.

CASE II.—E. V. E——, a man, thirty-six years of age, applied for treatment December 31, 1887, with a history of having sustained an injury to the left elbow, while in a state of intoxication, some twelve hours previously. The patient was a very fat man ; he was grossly addicted to alcohol, and during his treatment was frequently under its influence. The lower end of the humerus was found to be the seat of a comminuted fracture, the precise lesions in which could not be determined. It felt almost like the "bag of beans." and I judged that there must be several fragments. There was great deformity, and the joint was freely movable in all directions. The parts were moulded into shape as best one could, and a plaster splint applied with the elbow at a right angle. It was frequently examined. There was no union until the fortieth day, and even then it was not firm. Despite all efforts it became anchylosed, and at the request of the patient the angle was fixed at one hundred and fifteen degrees (he is a telegraph-operator and this is the most convenient position for him). He is now in a Christian home for the cure of his alcoholism.

CASE III.—F. R——, a boy, sixteen years of age, sought treatment at the hospital January 31, 1888, suffering from a typical T-shaped fracture of the left humerus. It was compound posteriorly, the lower end of the upper fragment having come down through the skin, making a wound a trifle smaller than the end of the little finger. The wound was very carefully dressed by Dr. Kimball, of the house-staff, who applied a right-angled splint, and advised the patient to seek house or hospital treatment. This, however, he refused to do, and insisted upon returning as an out-patient. I did not disturb the dressing until the seventh day, when it was removed under ether. The wound was found to be occluded; the position apparently good, though there was very much of swelling. Plaster applied with the elbow at a right angle ; union on the thirty first day ; flexion to seventy-five degrees ; extension to one hundred and ten degrees ; very much thickened. The patient was given careful advice as to baths, massage, use, and the like, but he never followed them and did not return to the hospital. I saw him a few days ago, and found the functions limited. There was flexion to eighty-five degrees and extension to one hundred and twenty-five degrees. Pronation and supination were about one-half. I could not judge well regarding the deformity, for the limb could not be sufficiently extended, but it seemed to be limited to a broadening of the condyles.

CASE IV.—J. W——, a boy, seven years of age, sought treatment for an injured elbow May 11, 1887. He was carefully examined under ether, and the left humerus found to be the seat of an epiphyseal separation through the condyles, the internal epicondyle being also broken off and the fissures apparently communicating. He was treated as were the preceding cases, and recovered without deformity. The function of extension, however, did not return, and at the end of the fourth month it was limited to one hundred and sixty-five degrees. The other motions were, however, perfect.

Of these four comminuted fractures one was discharged with a perfect result, one is perfect except that extension is fifteen degrees short, one is anchylosed, and one has but very limited functions ; still, I feel that you will agree with me that the latter two cases were very difficult ones. The anchylosed joint (the only one out of fifty, by the way, in which this result occurred) could not have been brought out differently, I think, by any method of treatment. The boy with the compound fracture paid no attention, after removal of the splint, to the functions, but simply carried the arm in the fixed position. He will neither move it nor allow others to do so.

The fiftieth case of my series, one which I judged as a separation of the trochlear epiphysis, has already been presented to this Section, and an account of it may be found in THE MEDICAL RECORD for March 17, 1888.

To recapitulate the results in the following fifty cases : Thirty-three completely regained the functions and present no deformity ; in seven the functions are a few degrees short of full ; in one they are very limited ; in two there is moderate deformity with a slight loss of function ; in one there is extreme gunstock deformity with complete use of the limb ; one is anchylosed, and three are yet in the second month of treatment.

If you will allow me to subtract the three [1] which are progressing favorably under present treatment, and to predict, as I think we honestly can, a full restoration of functions in the seven which are now a few degrees short, we shall have forty cures out of forty-seven cases, four fair results, and three distinctly bad. I must claim, however, that in two of these last three cases the result was unavoidable.

In most of the foregoing cases the injury was ascribed to a fall on the elbow, this varying from a slip on the sidewalk or a fall from a chair to a descent of ten feet ; in two to a fall on the hand, in one to the passage of a wagon-wheel, in one to a violent wrench to the elbow ; in several the nature of the accident was not known.

I do not think that, from a diagnostic point of view, very much real importance attaches to the nature of the injury ; our diagnosis must be based on the evidence gotten by physical examination of the affected part, and, as accurate diagnosis is indispensable to intelligent treatment, you will pardon me if I briefly allude to its more salient points.

---

[1] These are noted in the table as now completely cured (November 1, 1888).

No. of case.	Age.	Sex.	Date when first seen.	Lesion.	Results.		Remarks.
					a. Functional.	b. As to deformity.	
1..	11 yrs.	M.	Nov. 3, 1886....	Fracture through the internal epicondyle.	Perfect	None.	
2..	14 yrs..	M.	Dec. 15, 1886...	Fracture through the internal epicondyle.	Perfect	None.	
3..	11 yrs..	M.	Jan. 10, 1887...	Fracture through the internal epicondyle.	Perfect	None.	
4.	3 yrs..	F.	Feb. 21. 1887...	Fracture through the internal epicondyle.	Perfect	None.	
5..	17 yrs..	M.	March 12, 1887.	Fracture through the internal epicondyle.	Extension to 170 degrees	None.	
6..	45 yrs..	M.	June 1, 1887...	Fracture through the internal epicondyle.	Perfect	None.	
7..	31 yrs..	F.	June 11, 1887 ..	Fracture through the internal epicondyle	Perfect	None.	
8..	8 yrs..	M.	Nov. 15, 1887...	Fracture through the internal epicondyle.	Perfect	None.	
9..	14 yrs..	M.	Nov. 27, 1887...	Fracture through the internal epicondyle.	At end of 3d month: flexion to 75 degrees, extension to 145 degrees, then lost sight of.	None	This patient received no care at home, and could not be made to follow advice as to active motion, massage, etc.
10..	14 yrs..	M.	March 30, 1888.	Fracture through the internal epicondyle.	Perfect	None.	
11..	26 yrs..	M.	Nov. 13, 1886...	Fracture through the internal condyle entering joint.	Perfect	None.	
12..	10 yrs..	M.	Nov. 14, 1886...	Fracture through the internal condyle entering joint.	Perfect	None.	
13..	13 yrs..	M.	Feb. 2, 1887....	Fracture through the internal condyle entering joint.	Perfect	None.	
14..	41 yrs..	M.	Feb. 12, 1887 ..	Fracture through the internal condyle entering joint.	Extension about 5 degrees short of complete, otherwise perfect.	None	The functions were perfectly restored, Oct. 10, 1888.
15..	15 yrs..	M.	March 30, 1887.	Fracture through the internal condyle entering joint.	Perfect	None.	
16..	14 yrs.	M.	April 17, 1887 .	Fracture through the internal condyle entering joint.	Perfect	None	This boy was sent to a reformatory when the functions were yet a few degrees short of complete. I was told by his parents, however, that he regained them perfectly, and so note.
17..	12 yrs..	M.	April 27, 1887..	Fracture through the internal condyle entering joint.	Perfect	None.	
18..	9 yrs..	M.	Sept. 17, 1887	Fracture through the internal condyle entering joint.	Perfect	None.	
19..	12 yrs	M.	Nov. 4, 1887 ...	Fracture through the internal condyle entering joint.	Perfect, except extension; this 10 degrees short.	None.	
20..	2 yrs	F.	Nov 10, 1887...	Fracture through the internal condyle entering joint.	Perfect	None.	
21..	13 yrs.	M.	Feb. 13, 1888...	Fracture through the internal condyle entering joint.	Extension 10 degrees short	None.	
22..	32 yrs.	M.	April 10, 1888..	Fracture through the internal condyle entering joint.			Patient was under treatment when paper was read; result now noted as perfect in every way (Nov. 1, 1888).
23..	7 yrs..	M.	Oct. 8, 1886..	Fracture through the external condyle into joint.	Perfect	None.	
24..	3 yrs.	M.	Jan. 22, 1887...	Fracture through the external condyle into joint.	Perfect	External condyle prominent, externally displaced a trifle backward.	
25..	6 yrs	M.	Feb. 10, 1887.	Fracture through the external condyle into joint.	Extension 10 degrees short	External condyle much thickened and prominent.	
26..	3 yrs..	M.	March 13, 1887.	Fracture through the external condyle into joint.	Functions nearly perfect on fortieth day.	None	Patient sought with a view to ascertaining present condition, but cannot be found.
27..	6 yrs..	M.	May 15, 1887...	Fracture through the external condyle into joint.	Perfect	External condyle much thickened and very prominent.	
28..	7 yrs.	M.	June 13, 1887...	Fracture through the external condyle into joint.	Perfect	None.	
29..	11 yrs..	M.	July 27, 1887...	Fracture through the external condyle into joint.	Perfect	None.	
30..	5 yrs..	M.	Aug. 11, 1887 ..	Fracture through the external condyle into joint.	Perfect	None.	
31..	8 yrs..	M.	Oct. 15, 1887...	Fracture through the external condyle into joint.	Perfect	None.	
32..	4 yrs.	F.	Dec. 2. 1887....	Fracture through the external condyle into joint.	Flexion and extension both a little short of complete.	None.	
33..	6 yrs.	M.	Jan. 2, 1888....	Fracture through the external condyle into joint.	Perfect	None.	
34..	3 yrs..	M.	Jan. 8, 1888....	Fracture through the external condyle into joint.	Perfect	None.	
35..	3 yrs..	M.	Jan., 1888......	Fracture through the external condyle into joint.	Perfect	None.	
36..	7 yrs.	M.	March 9, 1888..	Fracture through the external condyle into joint.	Flexion to 80 degrees, extension to 145 degrees.	External condyle displaced backward, and prominent externally.	
37..	30 yrs..	F.	April 3, 1888...	Fracture through the external condyle into joint.	Under treatment when paper was read, but since discharged with a perfect result.		
38..	4 yrs..	F.	May 9, 1887...	Fracture through the base of the condyles, transverse.	Flexion 12 degrees short of complete, other functions normal.	None.	
39..	3 yrs..	F.	Sept. 13, 1887..	Fracture through the base of the condyles; transverse.	Perfect	None.	
40..	4 yrs..	M.	Oct. 9, 1887....	Fracture through the base of the condyles, transverse.	Perfect	None.	
41..	3 yrs..	F.	Sept. 13, 1887..	Fracture through condylar base: *oblique*.	Flexion 15 degrees short, otherwise complete.	Extreme gunstock deformity..	Patient was not brought back by parents unti thirty-five days after application of first splint (see previous history).
42..	29 yrs..	M.	Feb. 3, 1888....	Fracture through condylar base; *oblique*.	Perfect	None.	
43..	32 yrs..	M.	March 21, 1888.	Fracture through condylar base: *oblique*.	Patient under treatment when paper was read, has since perfectly recovered.		
44..	2 yrs..	F.	Jan. 22, 1887...	Diastasis through condyles	Perfect	None.	
45..	6 yrs..	M.	Sept. 2, 1887...	Diastasis through condyles	Extension to 157 degrees	None.	
46..	3 yrs..	F.	Oct. 14. 1887...	"T"-shaped	Perfect	None.	
47..	7 yrs..	M.	May 11, 1887...	Separation of epiphysis; meeting fracture through internal condyle.	Extension to 165 degrees	None.	
48..	36 yrs..	M.	Dec. 31, 1887...	Extreme comminution; simple	Anchylosis		See previous history.
49..	16 yrs..	M.	Jan. 31, 1888...	"T"-shaped; compound	Flexion to 85 degrees, extension to 125 degrees.		See previous history.
50..	8 yrs..	M.	....	Separation of trochlear epiphysis	Perfect	None.	

These I think to be the presence of bony crepitus and abnormal mobility. Disability, local pain, and tenderness, ecchymosis, and swelling are common to contusions and sprains as well as to fractures, though present, as a rule, to a greater degree in the latter. We are told to see that the bony prominences, the olecranon, head of the radius, and epicondyles bear their normal relation one to the other. This is good as far as it goes: it bars out dislocation, but there is frequently fracture without appreciable displacement.

Well-localized bony crepitus and a false point of motion are the evidences on which our diagnosis must be based.

By firmly grasping the humeral shaft with one hand and seizing the condyles transversely, "rocking" the lower part strongly on the upper will determine whether the condylar portion is attached or detached. Each epicondyle and condyle may in turn be subjected to a like manipulation. Should the base be broken off, one condyle must be rocked upon the other to determine the presence of three or more fragments. If much swelling be present it is not easy to grasp the condyles, yet I have found that steady, firm pressure will sink the fingers until they reach and hold the bony points.

Swelling obscures the outer condyle to a much greater extent than the inner. Even though the effusion be great, I have never had difficulty in grasping the latter. The manipulation should be gentle yet firm, and one should apply all due force to the bony parts. He who handles a traumatic elbow as lightly as he would if it contained eggs which he feared to break, will not, in all cases, arrive at the most accurate diagnosis.

Nor am I in sympathy with those who await a subsidence of the swelling before completing the diagnosis. It is better to work in the light than in the dark, and we can direct our remedial measures much more intelligently after learning of the integrity or lesion of the bony parts.

The examination is always more satisfactory when made under an anæsthetic, and it should be administered in all cases of doubtful diagnosis, or in those in which it does not seem advisable to subject the patient to the necessary pain. Joint-crepitus at the elbow is very misleading; when there is a moderate plastic exudation one articular surface grates upon the other in a most deceptive way. This can sometimes be obviated by having assistants hold the bones apart, but even then the force necessarily used in "rocking" the bony parts jars the joint. In these cases an anæsthetic is indispensable, and, even with its aid, diagnosis may be obscure. I have of late seen several such elbow-cases which presented themselves without luxation, yet in which, under ether, the bones of the forearm were very easily thrown backward, leaving the lower end of the humerus to project anteriorly and capable of thorough and satisfactory examination.

Treatment seeks to accomplish two prime ends. First, complete restoration of the joint-function; second, the avoidance of deformity.

Regarding the best way in which the elbow-motions may be regained, surgeons differ. The dictum was formerly laid down that passive motion should be begun early and repeated frequently, and the rule was thought to be a cardinal one.

The late Dr. Hamilton said of fractures through the base of the condyles: "Gentle passive motion should be applied as early as the seventh or eighth day and repeated every second or third day," while in fractures through the internal condyle he advised that passive motion be begun at the end of the first week, and that the splints be then left off. I think I am correct in supposing that this teaching is believed and followed by the larger number of practitioners to-day, and, although my observation has necessarily been limited, I do not hesitate to place myself with those who think such practice radically wrong.[1]

Do not the cases which I have shown and cited to you prove it safe to keep this joint still until such time as union is complete? In most of them the functions were practically perfect at the end of the third month, in some of them they were perfect at the middle of the second, and it is principally to demonstrate this that I have brought the subject before you.

Are like results gotten by the advocates of passive motion? It is said that the passive motion should be so slight as not to cause pain, but in each of the cases which have come to me with stiffened joint after the employment of this, the patient has averred that the surgeon's movements were painful.

Stimson[2] says: "I do not think early passive motion is necessary to prevent stiffness of the joint, and when it is painful, the pain lasting for some time, I believe it to be actually harmful by increasing and prolonging the inflammation." He also says: "The records of cases are filled with instances in which the joint has become almost or entirely rigid under treatment by passive motion, and then after the tenderness had ceased mobility has returned gradually under ordinary daily use of the limb." We have all seen such cases. Allis[1] says: "The sequel to these injuries is so much dreaded that authors and surgeons are most earnest in pointing out the necessity of early, and, if necessary, persistent passive motion. Some recommend that this feature be instituted even during the first week, others in the second, but all agree that it is never to be lost sight of. Upon this subject I desire only to state my own practice, not to recommend it. . . . I believe that it cannot hasten, but may greatly retard the cure."

Again, how can displacement be prevented if the parts are daily moved before there is union? The forearm bones are powerful levers through their attachment to the lower fragment, and must effect changes in its position. It was said that deformity was of no importance as long as the functions were restored. That the functions are of the greater value no one will deny, but if we can restore them without deformity it is surely our duty to do so.

The callus must be greater when the parts have been kept in motion, and this excessive deposit may of itself act as a mechanical impediment to flexion and extension.

Assuming, then, as I think we may, that deformity is more certainly avoided by keeping the parts at rest, in which position is this best effected? That a separated epicondyle is best replaced under flexion within a right angle I think nobody will deny, and I am equally sure that it is the best attitude in which to treat the transverse fracture through the epiphyseal line or through the base, traction on the forearm carefully drawing the lower fragment very well forward, as all tendency is toward its backward displacement. To be sure, this puts the triceps tendon on the stretch, but if the parts are held in place until the plaster dressing becomes firm they are well fixed and can hardly slip.

Dr. Allis, in the paper to which I have previously alluded, very strongly urges the position of full extension in the treatment of all of the classes, and he says that in his practice it has never resulted in what might be called deformity.

Dr. Allis adduces very ingenious arguments to show that when made splints or even roller bandages are applied in the flexed position, the broken outer condyle is sure to be drawn downward or the fractured inner condyle pushed upward, either case resulting in "gunstock" deformity.

The cases which are noted in this paper go to show that this is not always so, for nearly all were treated in the flexed position, and in but one was there the "gunstock."

And my own observation has tended to show that in fractures through the inner condyle extension favors anterior displacement of the lesser fragment, it being pushed forward by the olecranon, which strongly impinges upon it from behind.

That the gunstock deformity may be avoided by the extended position I quite admit, for then one may make the elbow-obliquity just what he desires—in short, cause it to correspond with that of the opposite limb; but this correction may, in some cases, be made at the expense of anterior or posterior displacement. I feel, however, that we are greatly indebted to Dr. Allis for showing us that extension will correct the gunstock, which is of much greater import than a slight anterior or posterior displacement; and if any given position would correct but one, I would make that one the former, always considering that the chosen angle did not hazard functional loss.

[2] Treatise on Fractures, p. 403.

[1] Annals of the Anatomical and Surgical Society, vol. ii., No. 8.

Stimson says, of the treatment of fractures through the outer condyle: "It will be found in practice that in some cases the flexed position, and in others the extended position, favors displacement of the radius, and the treatment must be varied accordingly." I think that the rule will apply equally to the internal condyle.[1] In fracture of either I would compare the extended limb with its fellow, and, if there was a loss of elbow obliquity, correct it by abduction and immobilize in a position of semiflexion.

In conclusion, I beg to express my thanks to Dr. W. T. Bull for kindly placing this material at my disposal, as well as for his frequent and wise counsel; also to Drs. P. E. Tieman, E. B. Dench, L. L. von Wedekind, and G. K. Swinburne, house-surgeons to the Chambers Street Hospital, for their careful and efficient assistance in the treatment of the cases.

18 EAST TWENTY-FOURTH STREET.

ASEPTIC CLIMATES WITHOUT ALTITUDE.

BY W. H. GEDDINGS, M.D.,

AIKEN, S. C.

AT the recent meeting of the American Climatological Association in Washington, opinion was divided as to whether altitude is an essential factor in the treatment of pulmonary phthisis, a large number of those present claiming that an aseptic atmosphere, with little or no elevation, was fully as efficacious as one at a higher altitude, many of them contending that dryness was even more important than elevation. One speaker, Dr. E. T. Bruen, of Philadelphia, maintained that instead of being an advantage altitude was undesirable, as it necessitated continuous residence, and in the event of recovery the patient could not return to his former home at sea-level. In this connection Dr. Vincent Y. Bowditch, in a very interesting paper, "The Relative Importance of Different Climatic Elements in the Treatment of Phthisis," cited Aiken, S. C., as a resort where, owing to great dryness of the atmosphere and soil, and at an insignificant elevation of only a few hundred feet, most excellent results had been obtained in the treatment of pulmonary phthisis, basing his assertion upon cases published by the writer in THE MEDICAL RECORD[2] several years ago, and upon his own experience with cases he had sent there. After hearing Dr. Bowditch's remarks I concluded that it would be opportune to present a brief paper on the subject; the more so because, in my previous articles on Aiken, published several years ago, I contented myself, as was then the custom, with simply giving an account of the meteorological phenomena of its climate. The modern medical climatologist, while acknowledging the necessity for accurate observations of temperature, rainfall, etc., is more especially desirous of information in regard to the purity of the atmosphere and its freedom from micro-organisms, and the physician in search of a health-resort for his phthisical patients wishes to know, above all things, the extent to which the air of the place proposed is aseptic. The meteorological factor most common to aseptic climates is a low degree of humidity. Warmth and moisture promote putrefaction, while dryness prevents it. It is a well-known fact that the carcasses of animals exposed to the dry air of Buenos Ayres, instead of becoming decomposed, are simply dried up, a method of preservation of which we have another example in the mummification of corpses on the dry plains of New Mexico; but the most remarkable instance of this nature was the desiccation of human remains in ancient Peru, where, according to Garcilaso, the bodies of the Incas were preserved, "perfect as in life, without so much as a hair or an eyebrow wanting." "In the great Temple of the Sun at Cuzco, their bodies, ranged on one side, and those of their queens on the other, sat clothed in their former princely attire upon chairs of gold, their heads inclined downward, covered with raven black or silver white hair, and their hands placidly crossed over their bosoms."[1]

Some twenty or thirty years ago warmth and equability of temperature were considered essential for pulmonary invalids, and as the latter is always associated with moisture the hapless victims of consumption were sent to semitropical insular resorts—the English to Madeira, and the Americans to Havana. A few were doubtlessly benefited, as the consumptive often is, even when the change of residence is to a climate worse than that in which he had previously lived; but these were the exceptions to the general rule, and most of them died, some of them even sooner than they would have done had they remained at home. But in those days consumption was regarded as an incurable disease, and as the balmy air of the South mitigated the severity of the cough, which was at that time considered one of the most important symptoms, the physician felt that he had done his best for his patient by placing him in an atmosphere where he could end his days in comparative comfort.

In the Roman Catholic Church there is a congregation of females known as the "Ladies of the Sacred Heart," with convents scattered over Europe and America. As is always the case with cloistered nuns, consumption is quite frequent among these ladies. Formerly, when an inmate of one of the houses in the United States showed symptoms of phthisis, she was immediately transferred to the convent in Havana, but as no benefit was derived from the change, some of them, who happened to be Canadians, pleaded to be allowed to end their days in their native land. The request was granted, and it was noticed that some of them, instead of dying, were improved by the change, and eventually recovered. Then came the Minnesota craze, and even in that extremely cold but comparatively dry climate the results were far better than in the moist, relaxing air of the South. A few still send patients to insular climates like Nassau or Bermuda, but most of the places which at present enjoy any reputation as resorts for phthisical patients are more or less dry, and, within reasonable limits, the dryer they are the better are the results. At the head of the list stand Colorado and New Mexico, with a mean annual relative humidity of forty-nine to sixty-one per cent.; next is Aiken with fifty-eight per cent., and then the Riviera with from sixty-four to sixty-eight per cent. That the ever-increasing popularity of dry, aseptic resorts is not the result of the bacterial hobby is proved by the fact that they came into vogue before Pasteur had published the results of his classic experiments, or Lister had immortalized his name, and revolutionized surgery, by the application of antiseptic principles to the treatment of wounds.

The investigations of the elder Bowditch, in the United States, and of Buchanan and Simon, in England, had established the coincidence of pulmonary consumption with soil moisture. "It is shown," says the latter, "to be a disease which develops itself in proportion as men are dwellers upon a humid soil." A glance at any geographical chart of the distribution of phthisis shows that it is most frequent on the sea-coast, on the shores of great lakes, and on the banks of large rivers, and that it diminishes in frequency as we leave these large bodies of water and approach the interior of the continent. Thus it is quite frequent in Lower Egypt, less so in Middle

---

[1] Dr. G. W. Gay (Boston Medical and Surgical Journal, vol. cviii., p. 492) recommends that in fractures through the external condyle the elbow be acutely flexed, in order to prevent anterior displacement of the head of the radius or of the fragment itself. While I have never treated the fracture by this position I have, since reading Dr. Gay's article, in two instances temporarily placed the broken elbow at an acute angle, and in each case the fragment was markedly thrown backward by the pressure of the radial head. I have not yet met with a case of broken outer condyle in which the head of the radius had become displaced in front of the fragment.

Egypt, and quite rare in Upper Egypt. There are doubtless many other agencies at work in the production of the tubercle bacillus, but no one familiar with pulmonary consumption can deny that moisture is the most essential of all the climatic factors in its development. Without moisture the bacillus appears to become inert and, for the time being, harmless. Making all due allowances for the protection afforded by a strong, healthy organism, and granting that Metschnikoff's phagocytes really possess the power of devouring and assimilating the invading bacilli, it still remains a remarkable fact that, inhaling constantly, as many of us do, especially physicians and nurses, these poisonous micro-organisms, there are so few cases of contagion. At the Brompton and Victoria Hospitals for Consumption we are told that pulmonary phthisis is not more common among the physicians and attendants than it is among the same class of persons in other institutions in London, and yet bacilli were found by Williams in large numbers in the air of the former hospital. With a view to determining the extent to which pulmonary phthisis is contagious I made it a practice, for a number of years, when examining married consumptives, to question them as to the possibility or probability of the husband having been infected by the wife or the wife by the husband, and in only two or three cases out of six hundred, one-half of whom were, or had been married, was this alleged to have been the case, and even in these the evidence was far from conclusive. Thus it appears that consumption is rarely contagious when the bacilli are conveyed through the medium of the air; but it is well known that the virus may be readily inoculated, as has been demonstrated by numerous experiments upon animals, and that it is frequently transmitted from parents to their children. Furthermore, cases of direct contagion are not uncommon. Of the latter we have an interesting example in the case described by Reich.[1] "A consumptive midwife was in the habit of removing by aspiration the mucous products which obstruct the primæ viæ of newly born infants, and, if the slightest asphyxia appeared, of insufflating the lungs with her own breath. Ten of these children, in whose family no predisposition existed, died of tuberculous meningitis, there being no epidemic of the kind in the district. The other midwife in the same neighborhood, who was healthy, had no cases of meningitis."

For a number of years I have resided near a large hotel which, during the winter, is frequented by a number of consumptives in every stage of their disease. These people, in expectorating, not infrequently miss the spittoon, and the muco-purulent sputa reach the carpet-covered floor. Others, again, use their pocket-handkerchiefs as cuspidors, or, as I have seen them do, they spread over the bed a large newspaper for that purpose, preserving it until the physician makes his visit in order that he may see the amount and character of the expectoration. Thus, even when not deposited upon the floor in the first instance, the sputa dries and portions of it, after being diffused through the atmosphere of the rooms, eventually settles upon the carpet. There, mixed with dust, the bacilli are frequently stirred up by sweeping, but, in obedience to the laws of gravity, soon return to their resting-place on the carpet. This goes on for months; day after day, week after week, the process is repeated, and it would be difficult to devise a better method of making a wholesale collection of tubercle bacilli.

After the close of the season these carpets are carted out to the lawn where, suspended between trees, they are beaten by eight or ten stalwart negroes. This operation, seldom completed in less than a week, evolves clouds of dust which these creatures inhale continually for eight or ten hours a day. The hard labor of itself necessitates deep inspiration, during which the bacilli-laden dust is drawn into the lungs, but this is made even more effective by the loud singing and yelling with which they keep time to the beating of the carpet. If infection of the lungs through the medium of dry air laden with bacilli were possible, it would certainly occur under conditions like the above; and yet, although I have made it my business to observe these men for six years, not a single case of phthisis has occurred among them, nor have they themselves the slightest fear of contracting the disease. This, however, is not the case with the washerwomen who wash the filthy pocket-handkerchiefs saturated with consumptive sputa. Among these several have succumbed to pulmonary phthisis, and many of them claim that their health has been seriously impaired by the work. They realize fully the danger to which they are exposed and have threatened to demand extra pay for this class of wash.

Here we have two classes of work-people of the same race, and some of them doubtless belonging to the same family, both inhaling large numbers of bacilli. Why do the carpet-beaters escape and why do the laundresses become infected? I believe that the reply to this question is that the carpet-beaters work in a dry atmosphere and the washerwomen in one saturated with steam and moisture. The dirty linen, covered with dry, decomposed sputa, all full of bacilli, are subjected to boiling. During the earlier stages of the process, and before the temperature becomes so high as to be incompatible with the vitality of the microbes, a cloud of ill-smelling, sickening vapor is evolved, and it is to this that those who become ill attribute their disease. Fortunately the climate is so mild that the work is done in the open air, otherwise the number of those infected would be much greater. In the case of the carpet-beaters, owing to the comparatively small amount of moisture in the atmosphere, the bacilli probably reach the air-passages either in a state of inactivity or so enfeebled that their entrance into the system is readily prevented by the means which nature has provided for that purpose, be they the phagocytes of Metschnikoff or some other agency. The ubiquity of the tubercle bacillus forces us to admit the existence of some such protecting power, for, were it otherwise, the greater proportion of mankind would sooner or later become tuberculous. The washerwomen, on the other hand, work in a warm, moist atmosphere, the conditions most favorable to bacterial life; the bacilli are stronger, and with increased vitality they become more dangerous—the safeguards provided by nature are less able to resist their attack, and, unless favored by an unusually strong constitution on the part of the person exposed, the bacilli gain the victory and the individual succumbs to the disease.

At the commencement of this article allusion was made to the almost complete abandonment of what was formerly regarded as the ideal climate for the consumptive. Nowhere, perhaps, in the domain of medicine has the profession been so completely swayed by the fashion of the hour as in the climatic treatment of pulmonary diseases.

Reviewing the past thirty years, we find the warm, moist climates of the tropics abandoned for the frigid air of Minnesota and Canada, but, these being found too severe, a healthy reaction took place and dry, temperate resorts, like those in the interior of South Carolina and Georgia, became deservedly popular. But, of all the pet theories of climato-therapy, none has proved so seductive, or excited more enthusiasm than that which is based upon altitude. Relying upon the statements of Jourdanet, Archibald Smith, and other travellers, it was claimed that the inhabitants of certain elevated regions were exempt from consumption.

A little later, at a time when the medical mind was deeply interested in the germ-theory, came the painstaking investigations of Miquel, showing that while the air of Paris contained 55,000 to every ten cubic metres, these steadily decreased with altitude until at a height of 13,122 feet they disappeared entirely. These facts and the wonderful success of Lister in the antiseptic treatment of wounds, suggested the application of the same theory to the climatic treatment of disease, and the climate of a place was no longer rated by its temperature, humidity, and other meteorological factors, but according to its freedom from micro-organisms. Aseptic climates became at once immensely popular, and as those of high mountains were alone supposed to be possessed of antiseptic properties, altitude at once became the grand factor in climatic therapeutics. For a number of years the opinions of the advocates of the altitude-theory were received with almost universal acceptation. Mountain-resorts were the only places where consumption could be cured; some few cases might improve elsewhere for a time, but permanent cure could only be achieved in these favored regions. Of late, however, it has occurred to many that the advocates of elevated climates were claiming too much, and that there might be aseptic regions nearer sea-level. On examining the grounds upon which the advocates of altitude base their claim to superiority in the treatment of consumption, we find that one of their chief arguments is the supposed immunity of the inhabitants of certain elevated districts from pulmonary phthisis, but we all know that it is equally rare in Madras, which is a seaport town, and in the Kirghiz steppes, which are actually below the level of the sea. We know, too, from the investigations of Küchenmeister, that the immunity of the mountaineer ceases as soon as he abandons stock-raising and farming and engages in factory work, as has been observed in the Erz and Riesen Gebirge. According to Germain Sée: "The best proof that altitude exercises only a questionable influence is that the inhabitants of elevated regions, when crowded together in confined localities, as is the case in workshops like those at Joux and Chaux-de-Fond, in the Swiss Jura, where, at an elevation of 1,100 mètres (3,609 feet), one finds as many consumptives as in the city of Berlin."[1]

---

[1] C. T. Williams: Pulmonary Consumption, p. 88. Philadelphia, 887.

Owing to the diminished pressure the air of high altitudes is more rarefied and contains less oxygen than at the level of the sea, and it is claimed that the diminution of this gas, by necessitating deeper and more frequent inspirations, tends to enlargement of the thorax and to better ventilation of the lungs, and thus acts as a prophylactic and curative agent in pulmonary consumption. This, however, does not accord with the fact just stated, that the mountaineer loses his immunity as soon as he ceases to live in the open air. The barometric pressure is the same in the factory as out of doors, and if he is exempt from the disease in the one instance and liable to it in the other the immunity must be due to some cause other than altitude. There is, as has been suggested by Schreiber,[2] a still stronger objection to the theory that the immunity is due to the diminished pressure of the atmosphere at high altitudes in the fact that the elevation at which immunity is said to occur varies with the latitude, ranging from 1,500 feet in the mountains of Silesia, and from 2,000 to 4,000 feet in the Alps, to from 6,000 to 10,000 feet in the Andes, and yet the rate at which the pressure diminishes is the same in every degree of latitude.

Referring to the immunity of the agricultural population of Switzerland, Jaccoud,[3] a warm defender of the altitude-theory, states, on the authority of Müller's statistics, that the degree of immunity is as great at 900 mètres as it is at 1,300 mètres and beyond that height. It is difficult to reconcile this statement with Miquel's observations, for, if the micro-organisms diminish with altitude, ought not the immunity to decrease in the same proportion?

The altitude-theory numbers among its supporters many of the most eminent specialists in Europe and America. Jaccoud and Herman Weber are among its champions abroad, while in this country Denison has devoted the best years of his life to its study; but, on the other hand, there are many no less distinguished who believe that altitude is not the factor to which are due the good results obtained at many of our mountain sanatoria. According to Nothnagel:[1] "The first essential for the well-being of the consumptive is *pure air*,[2] free from dust, atmospheric air free from all admixture with deleterious substances; to be at Davos in the Engadine, on the sea-coast, or on board of a ship, is immaterial, the determining element is *good, pure atmospheric air*." Herman Weber, the ablest, perhaps, of all the advocates of altitude, is no less emphatic: "All the climatic factors, elevation, temperature, etc., are all far less important for the consumptive patient than *purity of the atmosphere*." Rossbach[3] says: "In every variety of climate, and of climatic factors at the various climatic resorts—be they in the South or in the North—in the interior or on the coast, or on the sea itself—be they high or low—they have all one thing in common, sought for alike by the physician and layman, viz., *pure air, free from dust and smoke*. Dr. Loomis,[4] commenting upon a paper on mountain resorts, remarks that "it was not necessary to go to Colorado to find pure air; and besides, he did not believe that high altitude of itself was of the slightest importance. The great desideratum was *purity of the atmosphere*." "The air," says Oertel,[5] "must be rich in oxygen, dry, and free from dust."

Many pages might be filled with quotations like the above, but the repetition would be wearisome. I cannot, however, refrain from adding the opinion of that genial writer on medical climatology, Dr. Burnay Yeo.[6] "Wherever such air is found—pure dry air in unlimited amount—on the high table-lands of Mexico, in the elevated valleys of Switzerland, in the Kirghiz steppes of Asiatic Russia, in the pine-forests of Central Germany, and on the open sea—wherever men live a life in the open air, away from the emanations of cities, and from too close contact with humanity—in all such places we hear of consumption becoming arrested and cured. The bacillus tuberculosis seems to love hot moist air, and air freely charged with the exhalations of humanity; warmth and moisture seem to provoke it into special activity, while *dry air* at a comparatively low temperature seems to be inimical to it."

From the foregoing observations it appears to be quite evident that altitude is not of itself an essential factor in the climatic treatment of pulmonary consumption, and there is no reason why equally good aseptic climates may not be found at lower levels. I will now endeavor to prove that we have at Aiken, S. C., such an aseptic climate. The air there, like that of Colorado, is exceedingly dry, and has at times been even dryer than that of Denver, as was the case during the first four months of 1886, when the mean relative humidity of Denver was 61.09 per cent., and that of Aiken only 56.22 per cent. The dryness of Aiken is all the more remarkable when we compare it with other places in the same section of country. Thus the mean annual relative humidity at Aiken is fifty-eight per cent., while at Augusta, Ga., which is only seventeen miles distant, it is seventy per cent. At Charleston, one hundred and twenty miles eastward, it is seventy-four per cent., and at Thomasville, Ga., one hundred miles south, it is sixty five per cent. Other places may be equally dry, but if they are the humidity-figures have not been published, and up to the present time Aiken ranks as the dryest health-resort in the world outside of the protected region between the Rocky Mountains and the Sierras. This remarkable absence of moisture is due to topographical conditions, and especially to the dryness of its soil. Its elevation of less than

six hundred feet is comparatively insignificant, but, being much higher than the surrounding country and sloping down in every direction, water does not remain upon the surface, but is immediately drained off or is quickly absorbed by the porous soil. Being open on all sides the air circulates freely over the surface of the ground, promoting evaporation, and thus adding to the dryness of the air. The soil consists of porous sand, with a very slight amount of clay, and some idea of its dryness may be formed from the fact that there is no water nearer to the surface than eighty feet, the average depth of the wells being about one hundred and ten feet. The dryness of the air is also attested by the total absence of the gray moss which grows all over the South Atlantic States wherever there is sufficient moisture to sustain it. Guns and instruments seldom rust, nor does mould form readily on unused articles of leather. The chapping of the hands from dryness, observed in Colorado, occurs also in Aiken, but not to the same extent as in that excessively dry region.

I have dwelt upon the subject of dryness at some length, partly because it is the chief characteristic of the Aiken climate, but more especially because moisture is essential to bacterial life, and in the absence of a microscopical examination of the air there is no better test of its purity than that afforded by the psychrometer—the lower the relative humidity the more antiseptic the climate.

Let us now see to what extent this applies to Aiken. We know from the hygrometric records that its climate is very dry; have we any proof to show that it is equally aseptic? An extensive practice in that place, covering a period of twenty years, enables the writer to give an affirmative reply to this question. He has not only thoroughly studied every phase of its climate, but has also carefully noted its effects upon those in health as well as upon the sick, and upon the strength of these observations he will endeavor to prove that in this case, at least, purity of air is synonymous with its dryness.

During the civil war, and consequently long before tuberculosis was declared to be a parasitic infectious disease, Dr. E. S. Gaillard, then a medical director in the Southern Army, but later more widely known as the editor of the journal which bears his name, was directed by the Confederate War Department to select the best possible site for a convalescent hospital for sick and wounded soldiers. He chose Aiken, and afterward summed up its climatic advantages as follows: "Its peculiar dryness of atmosphere, its temperate and equable temperature, its freedom from sudden and violent changes, and the general prevalence of soft southerly and southwesterly breezes." His suggestion was never acted upon, nor am I prepared to indorse all that he says, but, on the whole, it is a fair estimate of the Aiken climate. Surgical cases are rare in Aiken, but every physician who has practised there has had occasion to remark the rapid healing of contused and lacerated wounds, usually with little or no suppuration. During the last season a gentleman while playing polo received a severe laceration of the scalp. The hemorrhage was quite free, and a groom standing by, with more zeal than discretion, and believing that the bleeding should be stopped at all hazards, covered the wound with a handful of earth and sand. Notwithstanding this rough treatment the wound healed rapidly, union taking place without any suppuration whatsoever.

Some years ago a stalwart negro accidentally discharged his pistol, the thirty-two-calibre ball passing through the second phalanx of the middle finger, shattering the bone, but leaving the integument and subjacent structures on either side in fair condition. Under simple dressings of carbolic acid the wound quickly healed without deformity, and leaving the finger as serviceable as it was prior to the accident.

Last summer a boy, a patient of Dr. A. H. Ashley, while attempting to clear the nipple of his gun by blowing through the muzzle, carelessly touched the trigger with his foot and discharged the piece. Fortunately the charge hung fire for an instant, and thus enabled him to partially withdraw his head. The load of small shot passed along the side of the face and inflicted a severe wound of the scalp, severing the auricle almost completely from its attachments, leaving it hanging by a small band of integument in front of the lobule. As the gun was only six inches from the face, the wound was not only contused and lacerated but also considerably burned by the powder. The temperature rose to 102.3° F., on the evening of the accident, but was normal the next morning and did not rise again during the time he was under treatment. The auricle was replaced and held in position by means of sutures, the whole being covered with a dressing of dry iodoform. There was no suppuration until the seventh day, when a very small amount of pus was observed. The patient did well and was discharged on the twentieth day.

I will give one more case, which occurred in my own practice several years ago, the details of which were published in the New York MEDICAL RECORD in 1875. A negro man, thirty-four years of age, fell across a wheelbarrow, breaking a porcelain cup which he had placed in the loose folds of his shirt. A fragment of the cup was driven through the abdominal walls, inflicting a wound through which a foot of small intestine protruded. After the accident he walked half a mile to the nearest drugstore, where I saw him about three quarters of an hour later. He was lying on the floor, cold and pulseless, and bleeding freely from the mesenteric veins. The protruding intestine, which was covered with dirt and fragments of china, was cleansed and replaced. Within fourteen days the wound was firmly united, and the patient returned to work. There was no suppuration and at no time did the temperature rise above 98.50° F. In obstetrical practice the results have been equally good. Puerperal fever is rare, and during the past twenty years, although I have had many difficult cases, necessitating the use of instruments and version, I can recall only two cases that terminated fatally, and in one of these death was caused by convulsions.

For the results in pulmonary phthisis I refer the reader to a series of articles published by me in this journal.[1] The tabulated results of these cases were as follows: Total number of cases, 69; in 13 of these the disease was arrested[1]—that is, the cough had ceased, the temperature was normal, the patients had increased in weight, and their general appearance indicated that for the time being, at least, they were restored to health; 29 were improved; 7 remained unchanged; 17 grew worse; and 3 died.[2] Adding the "arrests" to the "improved," we find that forty-two (or nearly two-thirds) of the cases derived more or less benefit from their residence in Aiken. This was at a time when physicians gave little attention to climato-therapy and its indications. If a patient had consumption, and had means sufficient to pay for the journey, he was forthwith ordered South. The consequence was that for a time the Southern resorts were crowded with cases too far advanced to derive benefit from climatic, or any other method of treatment. Year by year, however, there has been in this respect a marked improvement. Practitioners, realizing the folly and cruelty of sending patients to die among strangers, now exercise a sounder discrimination in the selection of their cases. The evil still exists, but is trifling compared to what it was when the above cases were published. Of late I have not had time to collect statistics, but I am safe in saying that, with the improvement in the character of the cases now sent South, the percentage of "arrests" and "improvements" at Aiken would be much greater than ten years ago.

In 1885 I published in this journal the histories of thirty-five successful cases of phthisis, all of which, except one, were treated at Aiken.[1] As three years have elapsed, it may interest the reader of that paper to know the further history of those cases. Of the thirty-five cases, four were lost sight of and have not been heard from; two committed suicide, after having remained well respectively five and eight years; one died last spring of tubercular meningitis, after having been apparently well for several years. This was the young "architect" from Pittsburg, one of the four selected cases published by Professor Charteris,[2] of Glasgow, as having recovered in Colorado, but who was never in that State except, perhaps, for a few months in summer. He always wintered at Aiken, and his "cure," if cure it can be called, was achieved at that place. After deducting the above, there remain twenty-seven cases to be accounted for, and these all, with one exception, were well when last seen or heard from. Of these, two were heard from eighteen years later, one after eleven years, one after nine years, three after eight years, two after seven years, five after six years, four after five years, three after four years, three after three years, two after two years, and one after one year. But one has relapsed, a little girl who, after remaining at her home in Portsmouth, N. H., for several years, contracted a pleuritis which was followed by a recrudescence of the tubercular affection. She is, however, still alive, and doing fairly well. In estimating the statistical results at a health-resort, it should be remembered that the cases are all private patients, whose attendance is, as a rule, too irregular to admit of the keeping of a complete record of the course of the disease. The cases I have published, although not selected, constitute less than one-fifteenth of the whole number treated, but these latter were necessarily excluded on account of the incompleteness of their case-histories. And as those which are continuously under the physician's care are usually the worst cases, it is fair to infer that, had the others been included, the percentage in which arrest or improvement took place would have been much higher. Many of the cases of incipient phthisis do so well after their arrival that they never consult the local physician, and no record is kept of their recovery.

---

[1] New York MEDICAL RECORD.

[2] Brehmer, in his excellent sanatorium at Gobersdorf, with every convenience and with absolute control over the movements and mode of life of his patients, claims to have cured thirteen per cent.

As previously stated, all modern writers on the climatic treatment of phthisis are unanimous that an aseptic air is the first essential in the management of that disease, and most of them agree with Burney Yeo[3] that pure air—pure, cool, dry air, in unlimited amount—is such an antiseptic agent. Dr. E. T. Bruen, in his paper on "The Climatic Treatment of Phthisis," read before the recent Congress of American Physicians and Surgeons, is no less emphatic in his recommendation of pure dry air. "The greatest benefit can be secured in the locality which possesses the purest air. A large percentage of ozone, the best-drained soil, atmospheric dryness without dust, and the greatest proportion of sunshiny days, and especially where these results are attainable at a moderate altitude. This latter feature should be considered important, because, should recovery occur, it may be possible to return to ordinary avocations with safety to health."

These, then, are the requirements of a health-resort for consumptives—pure, dry air at a moderate temperature, a dry and well-drained soil, and an abundance of sunshine. To what extent does Aiken meet these requirements? For the reply I refer the reader to the foregoing article, in which I have endeavored to show that the characteristics of the climate of Aiken are great purity and dryness of the air at a moderate temperature (the winter and spring mean being 58° F.), extreme dryness of the soil with complete absence of water to a depth of over one hundred feet, with a large preponderance of bright, clear weather. I would add that Dr. Bruen's last requirement is also met. The patient after recovery is not obliged to remain in Aiken, most of those who have regained their health there having been able to return home and resume their former avocations. My object in presenting this paper is not to underrate the usefulness of other resorts, but to prove that within thirty-six hours' ride of New York we have an antiseptic climate where consumption can be cured, its accessibility being not the least of its many advantages.

PEPSIN IN SURGERY.

By HENRY B. DOUGLASS, M.D.,

NEW YORK.

THE digestive ferments have only recently attained that state of perfection which enables the physician to use them successfully in the various derangements of the digestive tract, and as a solvent by local application to the diphtheritic membrane. This last use of the ferments suggested to me their use in surgical cases, and for some months past I have been using pepsin in surgical work. Pepsin is best applied in the form known as "pepsin in scales," or as an ointment with lanolin as a base:

℞ Pepsin.................................gr. 50
Lanolin.................................℥ ss
M.

The cases cited below well illustrate some of its applications.

1. In ulcerations.

CASE I.—Mrs. T—— had a varicose ulcer of leg covered with thin adherent membrane, beneath which were weak granulations. Around the ulcer for an area of two inches was an acute eczema. The ulcer was foul smelling. Pepsin ointment with cotton dressing was applied. In five days the dressing was removed. The eczematous patch was less inflamed, the discharges not offensive, and the membrane was entirely dissolved. The granulations were healthy. Bismuth was now applied and the ulcer was soon healed.

CASE II.—Mrs. M. D—— presented upon the middle of the tibial crest a varicose ulcer. The base of the ulcer was covered with a thick yellowish membrane. "Pepsin in scales" was applied to this ulcer. In one week the membrane had entirely disappeared and the ulcer was in a healthy condition.

CASE III.—M. D—— has a large epitheliomatous ulcer (rose cancer) of the neck. The centre of the ulcer is sloughing rapidly. The whole surface of granulations is covered with a membrane. The secretion from the ulcer is abundant and very foul. Pepsin ointment was applied daily to ulcer. In two days the surface of granulations was free from membrane and they looked smaller and red. Wherever the ointment was applied the sloughing ceased, but from the deeper parts of ulceration the discharge was unchanged.

2. In cicatricial contractions.

CASE I.—D. H. J—— two weeks ago had a periostitis of first phalanx of middle finger with cellulitis of palm of hand. The resulting abscess was lanced in two places. When he came under my observation the suppurative process had left much inflammatory induration in the palm of the hand, extending to the second phalanx. There was a small sinus leading to bare bone on the first phalanx. The patient was unable to flex the finger because the flexor tendon was adherent to its sheath, and could not extend it on account of the cicatricial contraction following the abscess. Pepsin ointment was applied to the palm, and the whole covered with a cotton dressing. In three days the sinus had closed and the cicatrix was much softer. After six days the palm was markedly less indurated, and the patient could flex the second phalanx completely. In ten days the patient was able to resume his employment as a cutter, and was fully able to hold the knife steadily in his hand.

CASE II.—Mrs. M. W—— had a parotid abscess complicating pyæmia. The abscess opened spontaneously and soon healed. There resulted much induration and considerable thickened cicatricial tissue, extending from the angle of the lower jaw to the zygoma, and from the sterno-mastoid muscle to the border of the masseter muscle. This cicatricial tissue produced anchylosis of the lower jaw on the affected side, so that the patient was unable to open her mouth enough to admit solid food. Pepsin ointment was applied twice daily. In one week there was marked improvement in opening and closing the mouth, and the tumor had nearly disappeared. In two weeks there was no trace of the swelling, and movements of the jaw were perfect.

[2] London Lancet, November 26, 1887.

[3] Ibid., p. 606, October 14, 1882.

Remarks: 1. In all ulcerations covered with a slough, or having a membranous base, pepsin is of use to digest this slough and bring about a healthy condition. 2. The efficiency of pepsin ceases when the slough has dissolved. 3. In cicatricial tissue causing anchylosis pepsin is of use by dissolving the cellular element. In this condition pepsin may act similarly to mercury and the iodides, or as a digestive.

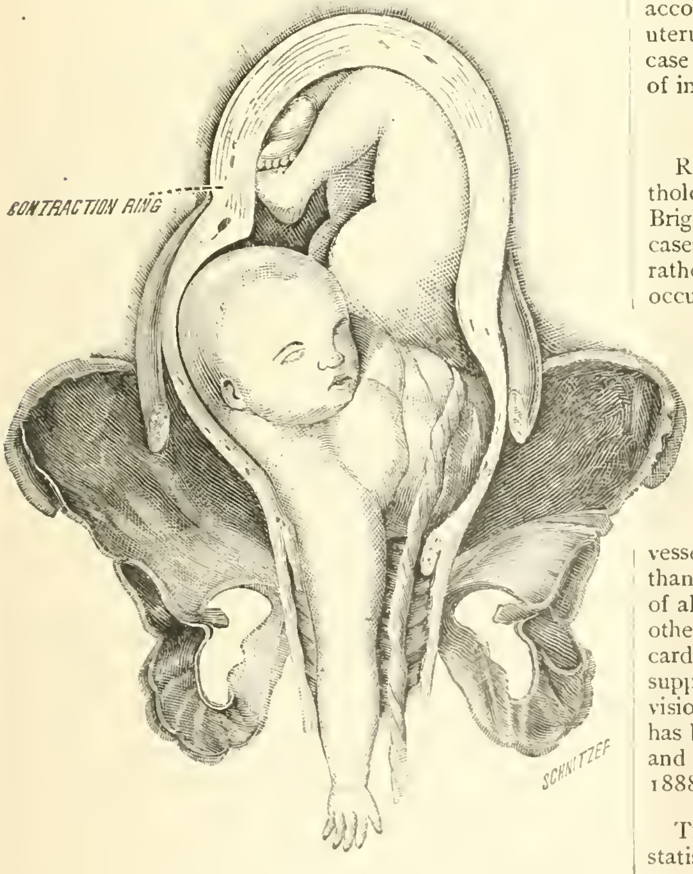
A CASE OF EMBRYOTOMY WITH BRAUN'S HOOK.[1]

By RICHARD STEIN, M.D.,

VISITING PHYSICIAN TO THE GERMAN DISPENSARY, NEW YORK.

Mrs. B——, multipara, aged thirty-two; previous labors normal; is now at full term. She had engaged a midwife for this confinement, for whom she sent as soon as labor set in. The midwife stayed with her about twenty hours, during which time patient had vigorous pains. Further particulars cannot be ascertained. I saw her in consultation with Dr. J. Metzger, about thirty hours after labor had begun. She was a well-built, middle sized woman, with normal pelvis. The labor-pains were very severe. The right arm of the fœtus and the severed umbilical cord hung out of the vagina. The head could be felt in the right iliac fossa. The ring of contraction (Bandl's ring) extended about two inches above the navel. The uterus was drawn tightly around the fœtus, and the right shoulder was deeply impacted in the small pelvis. After some difficulty the neck of the fœtus could be reached, and from there the examining finger passed over the chin into the mouth. The diagnosis was made of neglected transverse presentation. Rupture of the uterus was imminent. The child was dead.



The woman was placed in the dorsal position and ether administered. After emptying the bladder the left hand was passed into the vagina, gliding gently by the shoulder and reaching the neck of the fœtus after some difficulty. The index-finger and thumb encircled the neck, the palm of the operator's hand looking upward. Braun's hook, with the button turned down, was then inserted and applied around the neck, under the guidance of the left hand; it could play freely in the left palm. The head was severed within two or three minutes by means of one vigorous turn of the hook, which broke the spinal column and passed through the other soft parts of the fœtus without any trouble. The body was delivered by pulling gently on the protruding arm; the head was then easily extracted by inserting two fingers in the mouth and drawing gently, assisted by pressure from above. No post-partum hemorrhage. The patient made an excellent recovery.

This case shows that the decapitation-hook of Carl Braun can be employed with advantage, even in those cases where the neck of the fœtus can only be reached with some difficulty. It was not thought advisable to pull on the protruding arm to bring the neck down, on account of the great danger of additional strain to the uterus. The "cut" surface the instrument made in this case was surprisingly smooth, thus eliminating the danger of injury to the maternal parts.

Retinal Changes in Bright's Disease.—The pathology of the white patches in the retina occurring in Bright's disease is by no means clear. In the majority of cases the condition of the lesion is one of degeneration rather than that of inflammation. The white spots usually occur at some distance from the blood-vessels, and they are most common in cases of granular kidney. Dr. Maguire has found high arterial tension common to all cases of so-called albuminuric retinitis, and he is inclined to think that the degeneration is directly due to this tension. In Bright's disease the vessels become much contracted, consequently parts at a distance from the vessels suffer from lack of nutrition. It is well known that high arterial tension causes a diminished circulation through the smaller vessels, and consequently the retina becomes more than ever deprived of its blood supply. The rarity of albuminuric retinitis in cases of amyloid kidney, and other forms of Bright's disease where it is unusual to find cardiac hypertrophy or increased arterial tension, lends support to the theory advanced. The author has found vision improve in many of his cases where high tension has been combated by rest in bed and the use of calomel and salines.—*Birmingham Medical Review*, November, 1888.

The Proportion of the Sexes in Germany.—Recent statistics show that the number of men in Germany is constantly decreasing relatively to that of women, indeed there is an absolute decrease in the male population and an absolute increase in the female. The women outnumber the men in the proportion of 104.3 to 100, although there are more boys than girls. The disproportion is to be accounted for, therefore, by a greater mortality among boys, and by emigration. In Berlin, taking all ages together, there are 108 women to 100 men, of those between 60 and 70 years there are 150 women to 100 men, and between 70 and 80 the numbers are 196 to 100.

Clinical Department.

INTRACAPSULAR FRACTURE OF THE NECK OF THE FEMUR—PATIENT ABLE TO WALK WITH LITTLE DEFORMITY OR LAMENESS FOR THREE YEARS—NEW DISEASE THEN SETTING UP, WITH GREAT APPARENT SHORTENING AND DEFORMITY—DEATH.

By C. WINDSOR, M.D.,

BLOSSURG, PA.

The patient, a woman, aged seventy-four, had always enjoyed good general health, and was the mother of a large family of children. About March 25, 1885, while walking from church to her home, she fell upon the icy walk, was taken into a neighbor's house, and examined by Dr. Crandal and myself. Great pain was experienced on motion of the hip-joint, but nothing was found to justify opinion of anything other than bruise and sprain to hip-joint. She was removed to her home, where she remained in bed six weeks, at the end of which time she was able to move with some difficulty and the aid of canes to a chair or couch. At the end of ten weeks she was able to leave the house, and was more or less lame for about six months from date of injury. There was no change at *any* time in the relative position of the foot, no shortening nor deformity, or fulness at hip-joint at any time after six weeks from date of injury. She continued as well as ever during the succeeding three years.

About the middle of June, 1888, the patient began to experience a feeling of lameness in her back, as described by her, which increased to the extent of causing much inconvenience and suffering until July 6th, when she first consulted a physician, who attributed it to kidney disease, and gave remedies to relieve it on that hypothesis. The pain was felt over lower part of back, between hips, and more or less throughout the lumbar region. About July 8th or 9th she began to spend most of her time on the couch or bed, and continued suffering more or less in the same way, occasionally able to attend church, until about September 1st. I was called to see her September 7th, and found her complaining as described, and attributed her pains and her condition to rheumatism. Did not see her again until October 2d. Dr. Argue saw her September 25th, and corroborated opinion of lumbar rheumatism, and remedies were given for that disease, as had been given by myself. The patient continued in about the same condition, with exception of extension of pain to the right hip-joint during first week in October, suffering severely except when under opiates.

There was no change in the appearance of hip whatever until the night of October 18th, when her daughter undertook to relieve her sufferings by rubbing the joint with an anodyne liniment, and was startled to find the joint swollen and deformed, and sent hurriedly for me. I found the hip deformed, swollen, hot, and very painful. The greatest deformity was in the region of the great trochanter, the foot slightly *inverted*, and the limb shortened about two and a half inches. The condition in which I found the limb was a great puzzle to me, as it occurred so suddenly, without previous displacement at any time during life, or other similar injury to joint, but there was unmistakably a partial dislocation of the head of the femur on to dorsum of ilium. The pain was described as atrocious, prohibiting any handling of the limb. Hot fomentations were applied and anodynes pushed. The deformity and shortening increased until October 26th, when Dr. T. H. Squires was called in consultation. The shortening of limb had increased to seven and a half inches; there was almost *complete* inversion of the foot from the normal line, and the pelvis was tilted upward at an angle of about forty-five degrees in relation to the spinal column.

Firm but careful extension was made, and the foot slowly everted, and we were gratified to find the limb yielding until, after about fifteen minutes of continued effort, it was restored to within an inch, or one and a half inch of its normal length. Much relief was experienced after reduction, and, in fact, but little of the former severe pain returned again. The following day the patient was removed to a cot bed; and the second day extension was procured by weights attached to the foot over a pulley, and about five pounds was well borne until a day or two before death. During the last three weeks of her illness the most of her suffering was occasioned by a bed-sore over the sacral region, which was quite impossible to prevent, from the helplessness of the patient, and the necessity of continuing upon her back throughout the entire illness. There was no considerable alteration of temperature at any time, and the pulse varied from 100° F. to 110° F. during greater part of illness. As an autopsy could not be obtained the real condition of the hip-joint could not be ascertained, but from such manipulation as could be made after death I am convinced that it was due to a separation of the head of the femur at its surgical neck, and the drawing up of the bone on to the dorsum of the ilium, as in a dislocation at that site and in that direction. The only symptom that I have not mentioned that was marked during the early part of her illness was described as a sensation of numbness, a sort of dead feeling in the limb, that was spoken of by the patient during the early part of her disease. What significance it had in connection with the condition of the limb, as afterward developed, I cannot say.

Progress of Medical Science.

Real and False Anæmias.—There is no greater fault, according to Dr. Germain Sée, than that of giving iron to every pale patient one sees. If by anæmia we mean a deficiency of red blood-corpuscles, then there are very few real anæmias. In fact the real anæmias are but three in number. 1. Total anæmia, when from some great hemorrhage there is a diminution *en bloc* of all the elements of the blood. 2. Chlorosis, which is characterized by a functional defect in the hæmoglobine, which, according to Dr. Sée, does not mean that there is a diminished number of the globules, but a malady of the hæmoglobine itself while the number of the globules may remain the same. 3. The anæmia called spontaneous, where, without hemorrhage, there is a diminution of the hæmatics. Outside of these three types there is no real anæmia, but an immense number of false anæmias which Professor Sée divides into classes. First is the class of those patients who suffer from inanition from a number of causes, most prominent of which is insufficient nourishment; and just here iron will certainly do no good, while a good beefsteak will work wonders. Not only, however, does this class of poor, pale people consist of the really indigent classes, but also of the so-called anæmics who live according to a badly combined regimen. Another class of this form is the apnœics, or those who get pale from insufficient respiratory alimentation; these are the room-workers in a close atmosphere, and whose blood is quite rich in globules; all the same they are pale, since it is air they want and not iron. A further class is the worn-out or fatigued cases, who are pale and tired from hard work, be it muscular or mental, or again from too much alcoholic or sexual stimulation. Still one more class of false anæmias is the worn-out class from disease, albuminuria, diarrhœas, fevers, dropsy, etc.; but none of this lot are really anæmic, and if their blood-globules are counted they will be found as great in number as in healthy persons. Still another group is the poisoned class, who are cooks and workmen in noxious vapors, whose blood is charged with carbonic oxide, or carbonic acid gas, or lead-poisoning; they are also pale, but they have nothing to do with real anæmia. Finally, there is what Dr. Sée calls the virulent class of false anæmias, which includes scrofula, tuberculosis, syphilis, rheumatism, malaria, cancer, and other maladies which all produce paleness of the tissues, and a weakness which recalls the classic symptoms of anæmia, but the hæmatoscopic characters are quite different in all these cases from real anæmia, and the alteration of the blood is here of a virulent kind quite different from anæmia. This study of Dr. Sée's is of practical merit in a therapeutic point of view, because it teaches that iron is useless in a great number of these false anæmias, and it should not be given in a careless way to all pale patients, as it will only provoke digestive disorders that are worse than the patient's illness itself. In the present scientific era iron should be given where the indication is clearly shown by hæmatoscopic examination, and not distributed to all this mass of pale people, who should have the real cause of the pallid appearance carefully sought for, and the real remedy applied; whether it be suppression of the cause, as in inanition cases, where good food properly given will cure; or in the class of intoxication of the blood again, suppress the poisonous gases or the lead, etc.; while for the paleness resulting from diseases, it need not be told to an intelligent physician that he is at fault if he misses the real disease, and calls a false anæmia a real one, and gives iron in place of a disease medicine.—Paris Correspondence, *Philadelphia Medical Times*, November 5, 1888.

The Functions and Significance of the Faucial, Lingual, Pharyngeal, and Discrete Tonsils.—Dr. Spicer says in an article on the tonsils and their relation to affections of the throat and nose (*The Lancet*, October 27, 1888), that "it has long been known that lymphoid tissue, especially in the form of lymph-follicles, is very extensively massed together in the naso-pharynx and pharynx. The most conspicuous of these masses, the faucial tonsils, are very familiar pathologically. Likewise is that mass known as the pharyngeal or Luschka's tonsil, situated in the vault of the naso-pharynx, and which, when hypertrophied, forms post-nasal growths. To a less extent is appreciated that aggregation of crypts and follicles, called the lingual or fourth tonsil, situated at the base of the tongue between the circumvallate papillæ and the epiglottis, although its pathological conditions are among the most fruitful causes of many of the paræsthesiæ and dysæsthesiæ of the throat. To the above must be added those discrete patches of follicles on the pharyngeal walls which form the anatomical lesion in chronic granular pharyngitis; and an enumeration has been made of the principal groups concerned in morbid states of this area." Regarding the significance of these structures, he states that "the prevailing view appears to be that the faucial tonsils are essentially organs for the secretion of a lubricating fluid to aid in moistening the bolus of food before deglutition. Now, as the faucial tonsils are developmentally portions of the mucous membrane, there is no reason why they should not be provided with mucous glands to the same extent as the rest of the mucosa, and so secrete a little lubricating fluid, though insignificant in amount compared with that from the salivary glands. But that this secretion is quite a subsidiary and unimportant function of the faucial tonsils is palpable from the facts that in any tonsil, healthy or diseased, infantile or adult, the component tissue is lymphoid, arranged in follicles, with more or less fibrous tissue; and that the secreting mucous glands are very scanty, and, indeed, in the ordinary excised tonsil not demonstrable. No doubt, when these organs have been excised for hypertrophy, the fibroid changes have caused atrophy of whatever gland-tubes there might have been. Such fanciful theories as that the faucial tonsils are developed as compensatory organs for warming the inspired air when there is nasal obstruction, that they are reservoirs of nutriment like adipose tissue, and that their function is to keep the liquor amnii from passing into the fœtal pharynx, require no refutation. It is to Dr. Hingston Fox that we are chiefly indebted for a lucid exposition as to some of the main functions of the faucial tonsils. His conclusions are, firstly, that the faucial tonsils act in the prevention of fluid waste in the economy by reabsorbing the buccal secretions to a large extent after their work is done, and especially in the intervals of the deglutition acts; secondly, that they absorb certain of the elements of the food bolus as it is squeezed past them in deglutition; and, thirdly, that they form part of the blood-manufacturing system, and use up any nutriment remaining in the spent buccal secretions, acting, as he poetically expresses it, as 'nurseries for young leucocytes, planted by the waterside, and drawing their sustenance from the nutrient stream.'" He says further, that "there can be little doubt that the tonsils are the sites where the poison of scarlatina, measles, and diphtheria usually enters the system, since they are the parts first and most constantly, and often alone, visibly affected; and the lymphatic glands in direct communication with them most markedly, soonest, and most frequently involved. Faulty voice production and excessive use of the voice are very important causes of affections of all the tonsils. Excessive use demands excessive lubrication, and the latter implies excessive absorption on the part of all the lymphoid follicles. Hence the diffusiveness, chronicity, and obstinacy of the changes met with in the throats of clergymen, actors, and school teachers." The author finally submits these conclusions: "1. The significance of the various tonsils is in their palpable relation to the blood-manufacturing system and to the outpour of copious secretions. The relations of the tonsils to the rest of the organism can be well appreciated by comparing them with the relations of the sewage farm to the town whose refuse it makes use of, and to which it returns its elaborated products. 2. If any of the secretions delivered to the tonsils become contaminated in any way with irritating matters, whether generated in the system or introduced from without, those tonsils in physiological correlation with the affected secretion show irritative changes varying in degree. 3. The functions and affections of the various tonsils afford the key to the comprehension and scientific treatment—and the prevention—of many of the most intractable and recurrent disorders of the nose and throat."

Fluorescine in the Diagnosis of Corneal Lesions.—Dr. Straub recommends the instillation into the eye of a saturated solution of fluorescine, rendered slightly alkaline by the addition of 0.5 per cent. of soda, as a means of diagnosing corneal ulcers. Any portion of the cornea which is deprived of its epithelial investment will thereby be colored a bright green, while the sound portion is unaffected. The solution, he asserts, is perfectly innocuous.—*Weekblad van het Nederlandsch Tijdschrift vor Geneeskunde*, No. 16, 1888.

Resorcin in the Treatment of Keloid.—Dr. Justus Andeer, writing in *Der Fortschritt* of October 10, 1888, reports the case of a woman who was incapacitated for work on account of a large keloid on the right foot. A one-per cent. ointment of resorcin was applied, and in a short time all the painful symptoms disappeared, and the patient expressed herself as cured. Von Nussbaum has also recommended resorcin as a very efficient remedy for keloid. As the disease is usually regarded as practically incurable, a trial of resorcin would seem to recommend itself as worthy of being made. It is advisable to begin with a weak ointment and gradually to increase the strength according to the indications.

Patent Medicines.—In the United States there are said to be 563 manufactories of these goods, capital of $10,620,880, annual product valued at $14,682,492. New York State has 108 manufactories, employing capital of $4,513,430, putting out annually medicines valued at $3,339,178.

THE MEDICAL RECORD:

New York, December 22, 1888.

SCARLATINA DURING PREGNANCY AND IN THE PUERPERAL STAGE.

DR. ROBERT BOXALL has contributed to "The Transactions of the Obstetrical Society of London" a very long and elaborate paper "On Scarlatina during Pregnancy and in the Puerperal State." He presents a tabulated record of sixteen cases, and gives a bibliographical review of the subject. The conjunction of scarlatina with pregnancy and the puerperal state is fortunately not of frequent occurrence; when it does happen, however, serious complications may arise, and the conclusions of Dr. Boxall are therefore of much practical importance. The writer states distinctly at the outset that by puerperal scarlatina he means a true scarlet-fever infection, and not a septic fever with scarlatinous rash. He states in the beginning that—

"Infection by the poison of scarlet fever, either during pregnancy, during labor, or during the lying-in period is followed in the puerpera—

"1. By scarlatina, presenting for the most part the usual symptoms, *e.g.*, rash, sore-throat, and running the ordinary course of the disease.

"2. By scarlatina, presenting for the most part the usual symptoms and running the ordinary course of the disease, but associated with local and general lesions, *e.g.*, metritis, cellulitis, peritonitis, pyæmia, such as are produced by ordinary septic poison.

"3. By scarlatina, in which all the usual symptoms of the disease are absent, but in which local and general lesions, such as are produced by ordinary septic poison, are present; in a word, infection by the poison of scarlet fever is followed by a disease clinically undistinguishable from puerperal septicæmia, or from puerperal fever (as above defined)."

From an analysis of his cases he draws the following inferences:

1. As regards the time, with reference to labor, at which the disease shows itself—

a. That scarlatina almost invariably occurs within the first week of the puerperium, and its occurrence at a later period is extremely rare; and—

b. That in exceptional instances scarlatina may show itself during pregnancy, shortly before the onset of labor.

2. As regards the liability of pregnant and parturient women to scarlatinal infection, and the reciprocal influence existing between the latter and parturition—

a. That a woman exposed to the disease may become infected with scarlatina during pregnancy, during or after labor.

b. That the liability to infection is especially marked shortly before, and during the first few days after, delivery, but does not extend far into the puerperium.

c. That if infection occur during pregnancy, the onset of labor may be thereby precipitated.

d. That when infection takes place during or shortly after labor, the incubation period may be shortened; and, finally—

e. That the foregoing considerations are in themselves sufficient to explain the frequent onset of scarlatina during the first week of the puerperium, without the necessity of ascribing to scarlatina in pregnancy an incubation period exceeding that of ordinary scarlatina.

As regards symptoms he finds—

1. That during pregnancy the throat symptoms are unmodified, but that after delivery angina is rare.

2. That in scarlatina after delivery, *a.* subjective soreness is usually absent at the outset, and, even at a later stage, rarely causes much distress; *b*, signs of slight inflammation, though generally absent at the outset, may usually be observed on the second or third day of the attack; *c*, the cervical glands are usually affected, whether any change has been apparent in the throat or not.

As regards the labor he states that—

1. When labor occurs during the incubation period of scarlatina it runs for the most part its usual course, but the pains may exert a greater influence than usual on the mental condition of the patient; inertia, if induced, sets in late in the course of labor, and a peculiar and almost characteristic odor may be present.

2. When labor occurs during an attack of scarlatina, the pains are apt to be feeble throughout, inertia sets in early, and post-partum hemorrhage is liable to occur. The same peculiar odor may be present.

Some final observations are made as to the effect of the scarlatinal poison on the patient during the puerperium. Dr. Boxall thinks—

1. That involution of the uterus is not much, if at all, retarded.

2. That the slight and evanescent tenderness over the fundus, occasionally present at the very outset of the attack, is often due to exalted sensibility of the pelvic organs, and is rarely an indication of pelvic inflammation.

3. That, provided antiseptic precautions be taken, lacerations heal without difficulty, and the lochia, as a rule, do not become offensive.

4. That in some cases a peculiar, unpleasant odor may be observed.

5. That the lochia usually proceed naturally and cease about the usual time, but in many cases become red and free at the onset of the attack.

6. That the mammary secretion is frequently diminished, and sometimes arrested, as the result of the illness.

7. That infants kept at the breast are especially prone to scarlatina, probably from the mere fact of contact with the affected parent.

8. That when scarlatina shows itself in the mother during pregnancy the fœtus may or may not be affected *in utero.*

9. That when the mother receives infection shortly before delivery, the infant more frequently escapes, though it may be subsequently infected.

Some of Dr. Boxall's observations are trite, and some are trivial, but, taken altogether, his paper is a valuable one and deserves a more extended analysis than we can afford to give to it.

THE NAVAL MEDICAL SERVICE.

THE Annual Report of Surgeon-General Browne in 1888 shows that the condition of the Naval Medical Service is most creditable to its officers, despite the fact that many improvements, which have been long urgently desired, are still denied it. The subject of filling vacancies in the service is still in an unsatisfactory state. Medical Director Gorgas, President of the Board of Examiners, wrote in May last: "I have been greatly disappointed at the results of our work this year; seven of the twelve applicants were rejected physically, and but one of the others has passed professionally." There are at present eleven vacancies. The changes asked of Congress for the purpose of making the service more attractive are reasonable and just, and it is most unfortunate that the Surgeon-General still has to write that the bill providing such improvements "has no near prospect of a successful issue."

The morbidity and mortality statistics during 1887 show no marked changes from those of previous years. Our Navy contains 1,368 officers and 8,250 men, giving a total of 9,618. There were 11,473 cases of sickness reported, with 99 deaths, giving a mortality ratio per 1,000 of 10.29. As only 4 of these deaths are credited to *vulnus* and 10 to *submersio*, one may consider the sailor's life quite a healthy one in the present state of our international relations.

One of the most interesting features of naval medical work is the Museum of Hygiene. Under the efficient care of Surgeon Wells and his predecessors this museum has already become a centre for practical hygienic work and study, and it is destined, we trust, to become an institution having a widely beneficial influence. It should receive the generous support of our national Government.

THE DIGESTION OF CARBO-HYDRATES.

THE extensive use of artificial ferments as aids in digestion lends a practical interest to certain elaborate experiments recently conducted by Drs. A. Stutzer and A. Isbert upon the action of diastase and the peptic and pancreatic ferments upon digestible carbo-hydrates exclusive of fats (*Zeitschrift für physiologische Chemie*, xii., 1 and 2 hft.). The object of these experimenters was to see by what series of fermentative actions the greatest amount of carbohydrates could be digested. The substances used for experiment were hay, meal, and bread. A certain amount of these substances was mixed with solutions of ptyalin, pepsin, pancreatic ferments, and diastase.

We may say at once that the observers discovered the interesting fact that, by treating the above substances first with ptyalin solutions, then with pepsin solutions, and, finally, with pancreatic solutions, the largest amount of digestive action was obtained. It was found also that ptyalin, contrary to the usual belief, acted to a slight extent upon albuminous food. They also found that neutral ptyalin solutions acted even more strongly than feebly-alkaline solutions, and that diastase solutions produced nearly as good an effect as those of ptyalin. This is an important fact, clinically, for ptyalin is an expensive ferment, while malt diastase is comparatively cheap. Ptyalin solutions, alone, are more active than diastase, but when followed by a pepsin solution the digestive power of the two is just the same.

Pancreas solutions were found to act more feebly on carbo-hydrates than either ptyalin or malt diastase. The malt diastase, followed by a pancreas solution, digested less actively than did the ptyalin and pancreas series.

The general results of the experiments go to show that the saliva has an important rôle in digestion, and that, when it is not secreted properly, malt diastase can supply its place. It would also seem that the best time to take the malt is either just before or just after meals.

STATE MEDICAL EXAMINERS AND MEDICAL EDUCATION.

THE recently published report of the Virginia State Medical Examining Board contains some very interesting facts which will serve as valuable data for the continuance of the discussion in our own State. That this reform must come sooner or later very few doubt. It has a claim upon the professional mind analogous to the position occupied in the political world by high license and ballot reform. Instead of having to contend against the veto power of an obdurate governor, it finds its stumbling-blocks in the legislative hinderances placed before it by the medical colleges.

The report above alluded to covers the time from November, 1884, to October, 1888. During this time the Board examined 240 candidates, rejecting 54, or 22.5 per cent. Of the rejected men 25 made a second application, and 10 ran the gauntlet successfully. Of our own local institutions the College of Physicians and Surgeons sent up 3, all of whom passed; Bellevue, 6, with 1 rejection, and the University, 7, with 2 rejections. From Philadelphia, Jefferson sent 12, with 3 rejections; University of Pennsylvania, 2, both successful, while the 3 candidates from the Medico-Chirurgical College all succumbed. The largest number naturally came from the University of Virginia, 33, with only 1 rejection; a most creditable showing, and yet one which the history of this institution would lead us to expect.

It is pleasant to note the loyalty of the profession to the State Board. One institution demurred against its authority, and asked for its own graduates exemption from the provisions of the law. The request was most properly denied. In contrast to this is the college element of our own State, which opposes privately and corporately attempts to establish a State Board. It is but fair to the representatives of some of the larger institutions to exclude them from this category; this spirit of opposition is more rife in the smaller institutions. But some of the colleges, both large and small, are graduating men on the basis of the science of medicine of twenty-five years ago. As a Chicago journal well remarks: "Every new medical examining board created is a nail in the coffin of some unnecessary low-class medical college. The colleges that hope to survive must begin the work of reformation now."

The discussion of this question in conventions on social topics and similar gatherings shows the inevitable trend of public opinion. The bill outlined by Mr. Purington, and alluded to in The Record of November 24, shows this most conclusively. An impartial observer of the progress of medical education in this State, and particularly in this city, must admit that it has been retarded by the financial plan on which our colleges have been managed. This plan may have been a necessity, but nevertheless it has existed. The colleges are essentially stock companies, and the didactic faculties the stockholders. The receipts come from students' fees. Deduct the running expenses and we have left the dividends, and a very little calculation will show that some professors are paid very nearly fifty dollars a lecture, and all of them are not "spell binders" by any means. The minute they are willing to content themselves with smaller dividends the standard of medical education can be raised. The laborer is worthy of his hire indeed. But the whole matter of raising the standard of medical education is in the hands of a small minority of the profession, and this minority must be influenced by public opinion.

THE SURGICAL TREATMENT OF LUNG ABSCESS AND BRONCHIECTASIS.

The above subjects are treated of in a number of articles published in a recent issue of the *British Medical Journal.*

Mr. T. Pridgin Teale reports four cases of abscess of the lung treated by free incision and drainage; of these two recovered and two died. With regard to lung surgery Mr. Teale draws the following conclusions:

1. We are losing our fear of exposing the pleura and the lung, just as we have learnt, step by step, how to deal boldly and safely with the peritoneum.

2. The evil of admission of air into the pleural cavity is not the mere exposure of the pleural surface to the air, is not that the lung collapses by the mere admission of the air, but that where there is a fairly healthy lung and pleura the inrush of air reduces to a serious extent the mechanical power of the thoracic wall over the function of inspiration.

3. That in cases in which this mechanical difficulty threatens the life or impedes the recovery of the patient, surgery must decide upon the best method of closing the wound to the inrush of air, while allowing adequate drainage of any pus cavity to be carried on.

4. That the region of the diaphragm is a situation in which abscess amenable to surgical treatment frequently occurs, such abscesses often commencing below the diaphragm, and tending to discharge through the diaphragm and through the lung.

5. It seems probable that such abscesses can be more safely attacked through the lower angle of the thorax, provided there be dulness at the seat of puncture, than through the abdominal wall.

6. As to washing out the cavity of a large pleural or pulmonary or hepatic abscess, it is probable that antiseptic washing is of value in the early period, while the cavity is offensive; but that as soon as the secretion has become sweet, washing is not only unnecessary, but tends to disturb the comfort of the patient and retard his progress. If drainage be effective, so that fluid does not lodge, the fluid, which is sweet when secreted, should escape from the cavity before it has time to deteriorate.

7. As to the question of excision of portions of rib in treating empyema, on this point I am unable to speak from personal experience. The tendency of surgical opinion seems to be rather to reserve it for special and exceptional cases than to make it a general rule of practice.

Dr. David W. Finlay reported a case of bronchiectasis, in a boy of ten, treated by incision and drainage. The patient died about one month after the operation.

Dr. Finlay says, with regard to the surgical treatment of bronchiectasis: "Some cases have been undoubtedly benefited, a few have been cured; and with regard to others which have been reported, it may be said that some have been admittedly complicated with localized empyema, and that in the case of others the same complication may be reasonably suspected. In the latter class of cases it is not to be wondered at that cure resulted, inasmuch as the bronchiectatic condition was probably secondary to the empyema; and when the pus was drained by external opening the bronchial dilatations contracted and ceased to secrete pus. Of those which have been thought to be genuine cases of uncomplicated bronchiectasis, and in which incision of the lung had been practised, Dr. Finlay found records of twenty-two cases, inclusive of the present, and the results have been the following: Four appear to have been completely cured, three have been relieved or partially cured, and fifteen have died within varying periods after the operation. Of the fatal cases, no fewer than three have died from cerebral abscess."

The results, as may be seen, are not very brilliant. Still, in bad cases with copious fetid expectoration, and evidences of involvement of lung tissue, our operation offers the only possible means of saving the patient's life.

THE INFLUENCE OF THE DISCOVERY OF COCAINE UPON OPHTHALMIC SURGERY.

Since the discovery of the anæsthetic action of cocaine upon the conjunctiva so much has been written concerning its virtues, real and assumed, both as a local anæsthetic and as an internal remedy, that the subject would seem to be fairly well exhausted. It is of some interest, however, now that the experimental stage is past and cocaine has taken its place as one of the really valuable drugs that we possess, to see what effect it has had in modifying the treatment of affections of the eye.

At the last annual meeting of the Medical and Chirurgical Faculty of Maryland, Dr. Samuel Theobold presented a paper on this subject of which the following is a brief *résumé.* The action of the drug in causing anæmia of the conjunctiva and hardening of the cornea has had the effect of increasing the difficulty of subconjunctival tenotomy for the cure of strabismus. Not only is it less easy to pinch up a fold of the conjunctiva, but the muscle itself is in a state of tension. The difference is readily appreciated, the author says, when one has an opportunity to operate under chloroform anæsthesia after having performed a number of tenotomies under cocaine. One very noticeable change, and in many cases a matter of great convenience to the operator, is that the services of assistants can often be dispensed with, the patient himself, if old enough, being able to render all the aid that the surgeon requires.

There is a tendency at the present day for surgeons to return to the simpler operation of cataract extraction without iridectomy, and this is the direct result of the employment of cocaine. When the extraction is performed according to v. Graefe's method the only part of the operation, as a rule, that is painful is the excision of the iris, and, as the danger of prolapse of the iris is reduced to a minimum with the doing away of the risk of vomiting after chloroform or ether, ophthalmic surgeons are beginning to leave the iridectomy unperformed. Although the corneal section is more difficult under cocaine, by reason of the drying of this tissue, the disadvantage is compensated for by the fact that the patient is conscious and vision can therefore be tested.

Another modification in ophthalmic practice, which has come about as a result of the general employment of cocaine, is seen in the method of after-dressing. The former practice of applying compresses and bandages after operations, such as cataract extraction and iridectomy, is now being abandoned, and the eye is closed by simple strips of adhesive plaster, a method the advantages of which are obvious. This change is due to the fact that the necessity no longer exists for protecting the eye from the effects of vomiting and other accidents liable to occur when the patient is recovering from chloroform or ether anæsthesia.

Finally, in the treatment of granular lids the surgeon feels much less hesitation in using a remedy such as sulphate of copper, since the use of cocaine renders the application of this substance painless. The patient has no dread of the applications, and the surgeon is not deterred from making them as often as he thinks necessary because of the distress which they may cause.

IODISM.

THE action of iodine, and its compounds the iodides and iodoform, is naturally a subject of great interest, since few drugs are more extensively used in medicine and surgery. In a recent doctorate thesis, entitled "L'Iodisme," Dr. Elizabeth N. Bradley has gone over the subject most thoroughly, and collected pretty nearly all that is known upon it.

The history of the use of iodine is first given, and the mode of absorption, mode of action, and toxicity of iodine and the iodides discussed. Another chapter describes the action of the salts of iodine upon the various systems of the body. This includes, therefore, an account of iodism in all its forms.

The writer formulates fifteen conclusions regarding iodism.

Iodine itself, she says, is absorbed by the skin and mucous and serous membranes. It is carried to every part of the body by the circulation, and is eliminated by all the glands.

The different compounds of iodine cannot be absorbed by the skin and mucous or serous membranes without being first decomposed.

In certain conditions of lowered vitality, and especially in cardiac and renal disorders, with a morbid nervous irritability, there may be an augmentation of the physiological effects of iodine with symptoms of intoxication.

The phenomena of intoxication may develop rapidly or slowly, at the beginning or later on in the course of the medication.

The most common phenomenon of intoxication is a weak and rapid pulse, without any rise of temperature. The circulatory disorders in iodism are further characterized by œdema, which may be slight and effect only the face, or may involve the whole body, the glottis, the lungs, and even the brain.

These circulatory disorders may be followed by modifications in the renal excretion, viz., albuminuria, or even hæmaturia and anuria.

The nervous symptoms are such as pertain to cerebral anæmia or congestion. Hypochondriasis, general paralysis (?), uræmic convulsions, and coma are among the special disorders mentioned. On the part of the lungs, besides the symptoms of congestion and œdema, there may occur dyspnœa, irregular respiration, and apnœa.

The stomach and intestines show their revolt against iodine by nausea, vomiting, gastralgia, diarrhœa, or constipation. The most familar symptoms are those developed in the skin. Here we find the usual papular eruptions most often, but there have been also observed erythema, urticaria, and purpura. The joints may swell and become painful.

The general picture of iodine-poisoning is in a good many ways like that of the troubles for which iodine is prescribed, and the preachers of *similia similibus* will draw some comfort from Dr. Bradley's monograph.

News of the Week.

THE MONTEFIORE HOME FOR CHRONIC INVALIDS.—The new and beautiful building of this charity was opened and dedicated on the 18th inst. The Home can accommodate 180 patients, and is non-sectarian, though built and supported by Jews.

A MEMORIAL TRAINING-SCHOOL FOR NURSES has just been established at Pittsfield, Mass., by Mr. Henry W. Bishop, of Chicago, as an evidence of his appreciation of the value of the services rendered by trained nurses to his son during his fatal illness at Pittsfield, and also with a desire to aid in extending the widening field of usefulness of trained nurses.

TWO PHYSICIANS OF THIS CITY, Dr. Frank B. Carpenter and Dr. W. J. Martin, are lying ill in the New York Hospital. We are glad to learn that up to the time of writing they were both doing well.

AN IMPETUS TO OTOLOGY has been given by the illness of the present Emperor of Germany. It is said that twenty-five pamphlets on ear troubles have been published in Germany in the past five weeks.

DR. CHARCOT ON MEDICAL WOMEN.—Charcot is reported to have recently expressed the opinion that he could admit the use of women in a medical sense, but only for their own sex and for children. He was emphatic that this was the extent of their possibility in the profession.

DEATH FROM NOSEBLEED.—An item appears in the *Western Medical Reporter* to the effect that a young man recently died at the Presbyterian Hospital as the result of an uncontrollable nosebleed. This rare casualty was due to the fact that the patient had the hemorrhagic diathesis.

An Army Medical Board will be in session in New York City, N. Y., from May 1 to 31, 1889, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies. Persons desiring to present themselves for examination by the Board will make application for the necessary invitation to the Secretary of War before April 1, 1889, stating the place of birth, place and State of permanent residence, and enclosing certificates based on personal knowledge from at least two persons of repute, as to American citizenship, character, and moral habits. Testimonials as to professional standing, from professors of the medical college from which the applicant graduated, and of service in hospital from the authorities thereof, are also desirable. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a regular medical college, evidence of which, his diploma, must be submitted to the Board. Further information regarding the examinations and their nature may be obtained by addressing the Surgeon-General United States Army, Washington, D. C. Jno. Moore, Surgeon-General United States Army. Surgeon-General's Office, Washington, D. C., December 1, 1888.

Government and Sanitation.—Some comment has naturally been made upon the fact that the President's Message contained no reference to the yellow-fever epidemic, or the subject of national quarantine. It is to be hoped that, despite this, Congress will pay some attention to the matter of public health before it adjourns. It is, to be sure, looking quite actively after the health of its hogs, and a corps of eminent scientists is to investigate, or reinvestigate, the poor pig's bowels. No doubt the West will be more solidly Republican or Democratic if its pigs have less enteritis as a result of Republican or Democratic legislation. We should, however, like to see sanitary measures carried out on a somewhat broader and more systematic plan than is just now being adopted.

Increased Donations to the Cancer Hospital.—It was announced by the managers of the New York Cancer Hospital, yesterday, that Mr. John Jacob Astor had signified a desire to supplement his already munificent gifts to the institution by erecting a pavilion to be devoted exclusively to the use of men suffering from cancer. The present accommodations provide for women alone. The new building will cost, it is estimated, not far from $150,000. The entire amount of Mr. Astor's gifts to the hospital exceed $300,000.

The wife of General Cullum, another of the founders of the institution, left by her will certain properties in San Francisco, which, when available, will be devoted to the erection of a chapel in connection with the hospital. This money, some $50,000, is now in the hands of the trustees. Work on the Cullum Chapel and the new pavilion, which Mr. Astor desires to be a memorial of his wife, will soon be begun.

The Rights of a Consultant to Compensation.—The Orphans' Court of Philadelphia have recently (*Medical News*) decided the point that a consultant called in by the attending physician to a patient, separated from his family and mentally disabled, is entitled to just compensation. In the case in question the consultant, who was also the ordinary medical attendant, was absent from town, and his advice was given by letter. Against the claim for compensation it was objected that the consultant could not show contract with the patient, who did not personally summon him, nor was he called by a relative acting for the patient. The Orphans' Court, however, affirmed the contract on the ground of public policy, and awarded the claim; and further affirmed the right of the attending physician, under the circumstances, to summon counsel, if he deemed it desirable.

New York's Twenty-seven Private Hospitals involve an annual cost of $765,781.44. Of this amount $440,884.65 has to be raised by private subscription. The city hospitals, over eight in number, cost about $355,000 annually. The hospitals of New York, therefore, cost the people over a million of dollars annually.

Artificial Pupil through the Sclerotic Coat of the Eyeball.—Dr. George Strawbridge, of Philadelphia, describes in the *Medical News* an operation for trephining the sclerotic coat of the eyeball, near the cornea, and stitching a flap of the cornea over it, thus forming an artificial pupil. He first tried it with some success on six rabbits, and lately upon a man and a child with opaque corneæ. Dr. Strawbridge could not wait to see how the operations resulted before reporting his cases; he thinks, however, that the formation of a scleral pupil has a field of much usefulness.

The Training-school for Male Nurses at Bellevue Hospital was formally opened on December 17th. The building has accommodations for fifty persons. Out of one hundred and ten applicants twenty-two were selected. They will be given a two years' training similar to that of the female nurses.

The Hospital Saturday and Sunday Association has accepted the resignation of the Presbyterian Hospital, which institution proposes to work for itself alone. The Association adopted, among other resolutions, the following: "That this Association deeply deplores as unwise any division of general hospital funds under denominational direction, believing that such action would tend to deprive many other hospitals of this Association, partly under Presbyterian management, of their share of the moneys contributed by the general public to the general hospital fund of the city, and also tend to break up the most desirable spirit of unity which this Association seeks to establish."

Deer-horns as Medicine.—Quon Lun Wah has appealed to the Treasury Department from the decision of the Collector of Customs at New York, assessing duty at the rate of twenty-five per cent. *ad valorem* on certain so-called young deer-horns under the provision for medicinal preparations. It appears from a special report of the appraiser, that the so-called deer-horns are specially prepared as a medicine and are sold and used as such by the Chinese.

Fashions for the Dead.—A Glasgow paper has the following advertisement: "James Hodges continues to sell burying crapes ready made, and his wife's niece dresses dead corpses at as cheap a rate as was formerly done by her aunt, having not only been educated by her, but perfected in Edinburgh, from whence she has lately arrived with all the newest and best fashions for the dead."

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

MILK AS A VEHICLE FOR SCARLATINA—THE MORTON LECTURE ON CANCER—THE BRITISH MEDICAL ASSOCIATION—A UNIQUE CASE OF GOITRE—THE ETIOLOGY OF PUERPERAL FEVER—ACETONURIA AND ITS RELATION TO DIABETIC COMA.

London, December 1, 1888.

It is now about a year since the important debate at the Pathological Society on the relation between cow-disease and human scarlatina. The subject came to the front in the first instance in connection with an epidemic of scarlet fever in which the distribution of the disease was found to correspond closely with the distribution of milk from a particular dairy. An inquiry on behalf of the Local Government Board was carried on by Mr. W. H. Power and Dr. Klein. They reported that in this particular epidemic human sources of contagion might be excluded, and advanced the theory that the epidemic of scarlatina was due to the infection of the milk from the cows, who were found to be suffering from an eruptive disease on the teats and udders. Dr. George Buchanan, Medical Officer of the Local Government Board, regarded this disease as a modified form of scarlatina occurring in the cow, and Dr. Klein found the same micrococcus present as in human scarlatina. This opinion, however, did not find ready acceptance, and the subject was hotly debated at the Pathological Society, at which Professor Crookshank advanced the view that the eruptive disease in question was really cow-pox. Another aspect of the question is now presented by the publication as a blue-book of a "Report on Eruptive Diseases of the Teats and Udders of Cows in Relation to Scarlet Fever in Man," by Professor Brown, C.B., the veterinary surgeon attached to the Agricultural Department of the Privy Council Office. In this report Professor Brown combats the theory that the cow-disease in question was a form of scarlatina. He points out that it was not an isolated outbreak, and that though in one district an epidemic of scarlatina was apparently coincident in distribution with the area supplied from a particular dairy, yet that milk from other dairies containing cows similarly affected failed to produce scarlatina. He also thinks there was some evidence in favor of a possible human source of contagion whence the milk became infected. Although extremely valuable in itself, the mass of evidence collected by Professor Brown will probably not be regarded as conclusive. An important contribution to the question, and one which tells in favor of the opposite view, has recently been made by Dr. Hime, late Medical Officer of Health for Bradford. The occurrence of scarlatina in the immediate neighborhood of a dairy has frequently led to its epidemic spread through the agency of the milk. Dr. Hime, however, reported a case lately in which the occurrence of scarlatina in connection with a dairy was not followed by any spread of the disease among the customers supplied with milk from the dairy, although no special precautions were taken to prevent infection.

The "Morton Lecture" at the College of Surgeons, on cancer and cancerous diseases, was delivered on Thursday last by Sir Spencer Wells. The lecturer dwelt at some length on the important fact that for several years there has been a steady increase in the number of deaths from cancer, and that for many years past this increase has been greater than the proportional increase of population. He showed by means of tabulated statistics that this increase was more marked in England and Scotland than in Ireland. The mortality had also increased in recent years in the United States, and Sir Spencer Wells quoted Dr. Fordyce Barker's statement that the mortality from cancer in the city of New York had risen from four hundred to the million in 1875 to five hundred and thirty to the million. He also referred to what he termed the "remarkable fact" that at Frankfort-on-the-Main there had been a considerable decrease in the number of deaths (in proportion to the population) from mammary and uterine cancer during the twenty one years from 1863–83. The lecturer referred with regret to the reply of the Registrar-General to a memorial from the British Medical Association in which the desirability of tabulating separately cancers of each part of the body had been urged. The Registrar-General had not acceded to this, and as one reason for not doing so had pointed out the lack of precision with which many members of the profession stated causes of death in their certificates. Sir Spencer Wells admitted that the latter plea was not altogether unfounded, and said that we must all do our share of the work. The pathology of the disease was then briefly discussed, and the alleged microbic origin of cancerous growths was referred to. Scheurlen believed that he had found a specific microbe or bacillus, but this had been almost proved by Senger to be nothing more than a potato bacillus. So far as inoculation-experiments had gone, they were certainly against the microbic doctrine. We could, said Sir Spencer Wells, only admit that any disease was caused by a micro-organism when the latter had been isolated, cultivated outside the human body, and when the introduction of the cultured organism had led to an identical form of disease or growth. Coming to the practical aspects of the question, the lecturer discussed treatment. The latter should be thorough. In the case of mammary cancer his own experience was in favor of removing the entire gland in every case, except where the growths were small and close to the margin of the gland, or only affected outlying portions of it. When such growths were found, not in the mamma but in the axilla, he opposed removal of the breast, believing that many such tumors were neither connected with the breast nor with the lymphatic glands, but with the sweat-glands, as pointed out by Dr. Charles Creighton.

The recent publication in the *British Medical Journal* of a fac-simile of a few words written by the late Emperor of Germany, in which he complained of being ill-treated by one of his German medical attendants, has caused considerable comments in professional circles. It was felt by many that some steps should be taken in the name of British medicine to disavow the proceeding as unprofessional. With this object a memorial has just been presented to the Council of the British Medical Association, signed by some of the most eminent members of the profession. The Council have just had a meeting in which, after hearing Mr. Hart's explanation of the matter, they passed a unanimous resolution in which they expressed their regret that, under any circumstances, the document was published. They also strongly deprecate the publication of any details in violation of professional confidence. Sir William Jenner did not join in the memorial, but has taken the opportunity to resign his membership of the Association, and it is a significant fact that within the last few days Sir Morell Mackenzie has resigned his membership of the College of Physicians.

A somewhat remarkable case was shown by Dr. Stoker at the last meeting of the Medical Society of London. It was that of a patient who had suffered from goitre, but in whom repeated applications of the galvano-cautery to the nasal passages had resulted in a complete disappearance of the growth. The patient first came under his care in April last. Various modes of treatment afforded no relief. In June there were symptoms of rhinitis, and considerable thickening of the turbinated bones was found. The hypertrophied tissues were punctured and scarified with the galvanic wire. After the second or third application the goitre began to diminish, and it had now disappeared. The cauterizations had been continued up to the present time, at fortnightly intervals, other treatment being suspended. Dr. Stoker suggested that the nasal treatment had produced reflex irritation of the vaso-motor nerves, causing constriction of the blood-vessels in the gland and diminution of the hypertrophy, illustrating the intimate connection between the functions of the thyroid body and the vaso-motor system.

At the Medical and Chirurgical Society Dr. W. R. Smith read a paper on "The Etiology of Puerperal Fever," based on some researches carried on at the Brown Institution. Blood was obtained from the heart of a patient who had died from puerperal fever, and cultivations made on gelatine in the usual way. Blood was also obtained from the finger of a woman suffering from puerperal fever, and similar cultivation-experiments made. As the result of numerous observations, Dr. Smith had found that a micro-organism occurred in the blood of persons affected with puerperal septicæmia in considerable numbers in the form of streptococci. Culturally there were marked differences between it and other streptococci. Its action on mice was distinct and definite, and it could be distinctly distinguished from the erysipelas streptococcus of Fehleisen, and from the streptococcus pyogenes of Rosenbach. An animated discussion followed the reading of the paper.

At the same meeting of the Society a paper by Dr. Samuel West, on "Acetonuria and its Relation to Diabetic Coma," was read. He concluded that acetonuria was common in diabetes without coma, and that it was not constantly present in cases of diabetic coma. When present, it varied greatly from day to day without definite cause and independently of variations in the amount of sugar, and in the specific gravity. It might even disappear when coma developed. The iron reaction showed no relation either to coma or acetone. Both experiment and clinical observation therefore went to show that acetone could not be the cause of diabetic coma. Acetonuria, however, had a clinical value as indicating that the patient was in a more critical condition than when it was absent.

THE ASSOCIATION OF ACTING ASSISTANT SURGEONS.

To the Editor of The Medical Record.

Sir: As one of the members of the Association of Acting Assistant Surgeons of the United States Army, I wish to thank you for your very kindly given use of the columns of The Medical Record. We have a hard work before us, and many obstacles to overcome. In the first place, we are trying to obtain the names of the first appointments as Acting Assistant Surgeons United States Army, and as complete a list as possible from that date to this. We desire, so far as possible, to give the complete medical history of each Acting Assistant Surgeon, and we especially desire to obtain the names of those who have died from wounds and disease contracted while in the service, and also of those who have been killed in battle, either in the War of the Rebellion or in the Indian wars. All this information we intend to publish in book form, with some pages relating to the general history of the corps, etc.

You will readily understand what a difficult task this is, and how much we need the aid of medical men generally. Besides the publication of this book, we are trying to collect funds to place a suitable memorial tablet in the Post Chapel at Fort Leavenworth, Kan. The tablet is to be of brass, in the shape of a large Geneva cross with a background of *oak*-wood. The inscription is: "In memory of the Acting Assistant Surgeons of the United States Army who have fallen in the line of duty in the service of their country. R. I. P."

This will cost sixty dollars, and subscriptions will be gratefully received, from any who are interested in this memorial, by the Recorder of the Association of Acting Assistant Surgeons, Dr. W. Thornton Parker, Newport, R. I.

Many prominent surgeons and physicians in active practice to-day have been Acting Assistant Surgeons, and the list of names is in itself an honorable record for the Association. A deep interest and ready aid are shown in every direction, and the future success and usefulness of the Association seem to be beyond a doubt. All past and present Acting Assistant Surgeons of the United States Army are cordially invited to become members. Application blanks, etc., will be furnished by the Recorder.

W. Thornton Parker, M.D.

Newport, R. I., December 2, 1888.

THE ORGANIZATION OF THE ROOSEVELT HOSPITAL.

To the Editor of The Medical Record.

Sir: Will you not yield me space to correct a serious error of statement made by the Medical Board of the Roosevelt Hospital in the tribute paid—and entered on the minutes—to their late distinguished colleague, Dr. Sands?

"On May 30, 1882, he was appointed the sole attending surgeon to the Hospital. He had long advocated the plan of organization with a single responsible head to each department—a plan till then untried in any large hospital in the United States."

I held the same relative position, that of chief surgeon, having sole control of the surgical division of the State Emigrant Hospital, at Ward's Island, from 1873 to the end of the year 1880. The Hospital had 800 beds, with a capacity for 1,200. At no time—during my term of eight years' attendance—had I less than double the number of patients that the Roosevelt Hospital had at the time of Dr. Sands' service. Morris H. Henry, M.D.

581 Fifth Avenue, New York.

INGROWING TOE-NAIL.

To the Editor of The Medical Record.

Sir: An article on page 621 of The Medical Record for November 24, on methods of treating ingrowing toe-nail, leads me to remark that I have seen a number of cases which seem to warrant an opinion that the starting-point of many of these cases is a *corn*, caused by friction of the edge of the nail against its sulcus, and the retention of desquamated epithelium, which serves to increase the pressure. Once formed the corn gives rise to pain and to inflammation, which obliterates the first stage of the process.

Cutting the edge of the nail either on the side or the end, and allowing the granulations to grow up in advance of the protruding nail only makes a bad matter worse. It is often done by patients before consulting a physician, and, also, too often by physicians. The advice by a writer in the *Boston Medical and Surgical Journal*, not long since, that the soft tissues at the side of the nail, and not the nail, should be removed by operation, is far more rational, and produces a much more satisfactory result.

A sore toe is a small matter compared with much that is spoken of in medical journals; but the amount of suffering that this variety can cause entitles it to more consideration than it generally receives.

F. A. Castle, M.D.

New York, December 11, 1888.

ARE OPERATIONS FOR LACERATED CERVIX UTERI JUSTIFIABLE?

To the Editor of The Medical Record.

Sir: In your issue of December 15, 1888, the views of Dr. Walter F. Atlee on the subject of laceration of the cervix are republished from the *Pittsburg Medical Review*. Permit me a word in reply.

I know not whether you republished this tirade against the men "to whom we dare not apply the epithet of charlatan," as one of the curiosities of medical literature or not. Be that as it may, the article bears such a semblance of high authority, coming from one of that family which has given to the world one of its earliest, most courageous, and skilful ovariotomists, and offering the centennial experience of the brother and nephew of this justly eminent man, that I desire to investigate it.

These eminent obstetricians tell us that in one hundred years' experience they have never "found it advisable to sew up the neck of the womb for a tear." "And more than that, not in one case was there any reason to regret its not having been performed." "Mankind are indeed fearfully at the mercy of practitioners of medicine," is the sage deduction from the enormous "experience." Let us sift the enormous experience. The first intimation given to the world that laceration of the cervix may require surgical treatment appeared in Dr. Emmet's paper in *Am. Jour. of Obstet.*, ii., 1869. But the first paper which really bore fruit and aroused practical attention to the necessity for this operation was published in 1874 (*Am. Jour. of Obstet.*, vii., "Lacerations of the Cervix Uteri as a Frequent and Unrecognized Cause of Disease," Thomas A. Emmet, M.D.). It is therefore to be presumed that, since Dr. Atlee's father died in 1881, the conversation referred to was held just seven years after the laceration of the cervix began to be looked for as cause of uterine disease. Thus dwindles the experience of one hundred years, and with it the significance of its argumentative value.

Has any individual, be he ever so eminent, the right to decide upon an operation when he acknowledges that he has not once performed this operation, despite the fact that a host of justly eminent gynecologists are daily recognizing it as a radical remedy for the removal of chronic uterine catarrh, "ulcerations," erosions, etc.? To quote Dr. Noeggerath in this cause may sustain it with those who are unacquainted with that eminent gentleman's record in this city. As the discoverer of gonorrhœa as an important factor in diseases of the uterus and its appendages, Dr. Noeggerath has won for himself deserved fame as an original investigator. He stood alone, in opposition to Emmet's operation, in the staff of the Woman's Hospital, against men like Marion Sims, Emmet, Thomas, Hunter, Lee, and a host of others who have since that time made American gynecology famous. Failing in his efforts to dislodge Emmet's operation from the high esteem which its marvellous results have won for it, this pertinacious gentleman is now fighting it in Germany. Whether he will be as successful in this quixotic undertaking as he was in convincing his German confrères that sixteen per cent. of the women in New York city suffer from gonorrhœa remains to be seen. Dr. Atlee says:

"Some thirty years ago my old master, Nélaton, told me that certain diseases of the neck of the womb were *le pâturage des charlatans*. Since then the pasture-ground has become more extensive; it extends to the womb itself, and all its appendages, and many grow fat thereon to whom we dare not apply the epithet of charlatan."

The truth of this statement (barring the innuendo) proves the fallacy of Dr. Atlee's deduction. Judging from my personal experience, which unhappily is only a trifle over one-fourth of a hundred years, and from the observation of the extensive practice of others, but chiefly from a careful study of this subject, the results of which I have published ("The Therapeutic Significance of the Cervical Follicles," New York *Medical Journal*, June 27 and July 4, 1885), physicians no longer "grow fat" from the diseases of the neck of the uterus, but their work is now more often directed to the womb itself and its appendages. Many practitioners who have kept abreast of the advances in gynecology may testify how, in former years, women were wont to visit the office twice or three times a week for the purpose of having the uterus cauterized, leeched, brushed with iodine, tannin, and other astringents, or to have pessaries adjusted, and how greatly this number has diminished since they have removed the diseased structures by Emmet's operation. The aim of the latter is not to "sew up" the laceration, as Dr. Atlee puts it, but the removal of the diseased tissues which invariably surround many, though not all, existing lacerations. The erosions, ulcerations, leucorrhœas are radically removed, and the cervix is restored to its pristine shape and functions. Moreover, the size of the uterus is diminished, the congestions of the pelvic vessels removed, and the consequent abolition of the backaches, leucorrhœa, and retroversions due to the latter has vastly diminished the number of those office-patients who formerly came to have the "neck of the womb treated." Thus Emmet's operation for lacerated cervix, so far from causing us to "grow fat," has made decided inroads upon the income of the practitioner. And if Dr. Atlee would only be persuaded to become even a moderate follower of this corypheus, he will discover that *he* will more fully "recognize the high responsibilities and duties" on which he so admirably reads us a homily.

In the essay referred to above I have fully entered into the objects and results of the operation for lacerated cervix, and I have shown that the same results are aimed at by the Germans in the operations for excising the diseased mucosa, devised by Carl Schroeder, Hegar, Simon, and Martin. Dr. Emmet's position has been so misunderstood that he has really become discouraged; and I have heard him inveigh bitterly against the practice of superficial denudation, saying that he believed his operation is doing more harm than good because of its not being understood. Let me quote a description from Hegar and Kaltenbach (1881, p. 139), the great German textbook for gynecological operations: "While the assistant holds the lips of the os uteri on a stretch, the edges of the tear are freshened smoothly and thoroughly by knife or scissors; the freshened surfaces are brought together by needles," etc. Again, the following description of an operation for lacerated cervix I find in *The Chironian* (November 9, 1888): "Operation was made as follows by Dr. Helmuth: The lips of the laceration were denuded of membrane and then silver sutures introduced on each side," etc.

What caricatures on Emmet's operation these are, anyone who has seen Dr. Emmet labor from half an hour to an hour over a lacerated cervix, digging and snipping away diseased structures, glands, and "cicatricial tissue," will readily appreciate. Dr. Emmet never operates for lacerated cervix unless there are symptoms demanding it. Having followed his operations in the Woman's Hospital for many years, I feel authorized to make these statements.

In conclusion, I beg to say that until the profession obtains, from unbiassed sources, the information that the operation for lacerated cervix has failed, in a reasonably large number of cases, to remove the diseases for whose subdual it was devised, we must remain its adherents and advocates.

SIMON BARUCH, M.D.

47 EAST SIXTIETH STREET, December 17, 1888.

AN UNUSUAL RESULT OF A COMMON ACCIDENT.—In Vienna, recently, a man was buried under a mass of earth falling from the side of a deep ditch which he was digging. The earth covered his entire body, the head only being free. He died from the results of the injury, and at the autopsy a large swelling, the size of a man's head was found on the neck. Examination showed this to be the lungs and heart which had been forced up out of the thorax. The intestines had been forced up through a rupture in the diaphragm into the chest cavity, and the liver and spleen were extensively lacerated.

PROPHYLAXIS OF BERIBERI.—Drs. MacGillavry, Pekelharing, and Van Leest have been appointed by the Dutch government a commission to study the cause of beriberi and to search for some means for its prevention

DR. AGNEW AND THE NEW YORK PATHOLOGICAL SOCIETY — A BIOGRAPHICAL SKETCH.

By JOHN C. PETERS, M.D.,

NEW YORK.

Dr. Cornelius Rea Agnew joined this Society in 1853, when he was only twenty-three years of age, and remained a most worthy, although generally a non-active member, almost all the rest of his useful life, or for the long period of thirty-three years.

Few of our members, except the treasurer and those officers who are obliged to study the records of membership, even yet know that he was so long one of our colleagues, for he had scarcely attended any of our meetings for twenty years or more. He remained a member doubtless because he was fully impressed not only with the great usefulness of this Society, but of its absolute necessity as a great training and finishing school for all scientific physicians and surgeons. He was probably proud of its record, for I think he knew that it is the oldest pathological society in the world, and the original upon which the London, Dublin, Philadelphia and others had been modelled. I also believe he was grateful for the benefits he had received from it in his earlier years, and anxious to secure similar ones to all his successors.

He belonged to that small class of broad-minded and generous men, who, having labored long and earnestly in a great medical society like ours, do not lose their interest in it when they are no longer able to take part in its proceedings They know without prompting that they can always help to maintain its usefulness and dignity with very little material aid. They know that the outgoes of all scientific bodies are necessarily always large, and the incomes are usually comparatively small, and that it is vitally important that old friends and members should not fall off except by death or disability. This Society has been reasonably fortunate in such friends. Thomas M. Markoe, Gustavus A. Sabine, and Isaac E. Taylor have been our friends and benefactors since 1844, or for forty-four years, yet none but some of our oldest members have ever seen them here. The same may be said of Dr. George A. Peters, from 1847; Fordyce Barker, from 1850; John C. Dalton, William Detmold, Thomas Addis Emmet, and Cornelius Agnew, from 1853; Elsworth Eliot, T. Gaillard Thomas, and Henry B. Sands, from 1855; James R. Leaming, since 1856; William H. Draper and George F. Shrady, from 1858; Abraham Jacobi and Alfred L. Loomis, since 1860; Edward G. Janeway, from 1867; and many others for shorter periods. All these are comparatively non-active members, but most useful silent partners. The only active original members now left are Lewis A. Sayre and John C. Peters.

Dr. Agnew was nominated for membership by Drs. John T. Metcalfe and Thomas M. Markoe. He was well prepared, as he had passed through Columbia College; had studied under that great and brilliant surgeon John Kearney Rogers; had graduated from the College of Physicians and Surgeons in 1852, and had finally completed a full three years' term of service in the New York Hospital. The first specimens which he presented was a staphylomatous eye, a stomach corroded by sulphuric acid, an amputated arm, fractures of the ribs, rupture of the spleen, ulcerations of the small intestines, and typhoid fever without diarrhœa, fatty degeneration of the kidneys and the like.

He came to us when Alonzo Clark had already been engaged for ten years in those brilliant and almost unrivalled presentations and descriptions of disease which he was spared twenty years more to instruct and delight us with.

In Dr. Agnew's first year Dr. Clark presented and graphically described 49 specimens; for he often brought 3 or 4 at one meeting, and once came with 10. Dr. Markoe exhibited 16; Dr. Metcalfe, 14; Dr. Sayre, 18; Willard Parker, 10; John A. Swett, 9; Dr. Lidell and Alfred C. Post, each 8; Dr. Peaslee, 7; and Dr. Van Buren, 5.

Dr. Clark was Olympian in size and symmetry, cast in the largest and most beautiful mould, and seemingly more than one man in body and mind. Dr. Peaslee was equally tall, but far more slender, as white as a ghost, but lithe in body and mind, accurate in knowledge, and always ready and even brilliant in discourse, but he had a very sharp nose. Dr. Parker was also very tall, but truly elegant in face and figure, with the sunniest expression of general kindliness, yet capable of immense and quick physical and mental work. Dr. Van Buren was large in every way, heavy and sturdy in body, honest and precise, with a head rather less Websterian than Dr. Clark's, and often tip tilted back as if by an extra joint in his neck. Dr. Swett was delicately built, like the late Dr. Robert Watts, had the quaintest and most curious, but pleasant and intelligent expression and actions, and was one of the most scientific pathologists and diagnosticians that has ever appeared in New York. He was the first chairman and transient President of this Society. Dr. Post was short and strong, like Dr. Agnew, an equally devout Christian, an excellent and devoted surgeon, a most accurate linguist, and a very scientific man.

Dr. Agnew and all others must have been deeply impressed by the discussions between these able men. But soon he went to Dublin, London, and Paris to study diseases of the eye and ear. On his return he resumed his connection with this Society, and as he had been appointed Surgeon to the New York Eye and Ear Infirmary, he began to bring extirpated eyes for our instruction, and to propose new members, and to present their papers and specimens. The average attendance then was from twenty to thirty up to forty-five and forty-eight.

His private practice quickly became enormous, and his religious, patriotic, and philanthropic tendencies led him into many almost gigantic enterprises.

He came of French Huguenot and Scotch Presbyterian blood, and

"Early heard the voice of God,
And Angels to his sight appeared,
Crowning the glorious hills of Paradise."

He soon became a Director of the New York Tract Society and of the Young Men's Christian Association; an Elder and Trustee of the Fifth Avenue Presbyterian Church, and of various mission chapels.

He was active in all the State, County, and City medical societies, especially the Surgical, Ophthalmological, and Otological.

At the outbreak of the civil war he became Surgeon General of the State of New York under Governor Morgan. He decided, as far as one man could, that

"Our troops should lift their banners up
And our navies spread their flags abroad."

He sounded the alarm to Christian soldiers:

"Soldiers of Christ arise
And put your armor on,
Strong is the strength which God supplies,
And from strength to strength goes on."

He earnestly believed, like a true Puritan,

"'Tis God that guards me with His might
And gives me His holy sword to wield."

But Dr. Agnew was a truly humane Christian soldier. He was one of the organizers and most active members of the United States Sanitary Commission. He cheerfully helped sick and wounded Confederates, miserable negroes, Indians, scouts, tramps, and gypsies. He made great sacrifices of time, money, and his practice, in doing all this, but it all came back to him.

Then he helped to found the Union League Club, became a trustee of the public schools, also of Columbia College and the School of Mines, and occupied almost scores of other public positions, professional and non-professional, including those of the Presidency of the

Medical Society of the State of New York, down to the Governorship of the Women's Hospital and of the Poughkeepsie Insane Asylum. Yet, wonderful to relate, he never lost his private practice, his skillin operating, or his leadership in his specialty.

Dr. Agnew was below the average height, barely five feet six inches tall. When he joined this Society he weighed not more than one hundred and twenty pounds, but he had a perfectly formed, symmetrical, and active frame, capable of bearing great and prolonged mental and physical efforts. His face was very speaking, frank, and handsome; his forehead unusually broad; his eyes calm, clear, bright, and hazel, but often twinkling with pleasure; his mouth was expressive of great decision and firmness; and his whole bearing that of wisdom and integrity. His manners were wonderfully winning, so that he attracted attention and made friends everywhere. All recognized him as the sternest and purest of moralists, yet the most pleasant and helpful of friends. He was a man possessed with deep religious fervor, yet free from self-righteousness and intolerance. His love to his neighbor was proportionately as great as his love to his God, and that was very great.

In his latter years his figure only grew more firm and well set; his back flatter and more straight; his shoulders more square and soldierly. There was not the least suggestion of a slouch anywhere. He had enjoyed uninterrupted good health up to his last short sickness; the reward of a splendid constitution and a life of purity, simplicity, and frugality almost without a parallel.

He and those other great Christian physicians and surgeons, Post, Peaslee, Parker, and Sands, made religion pleasant and attractive to all. His death was magnificent in its courage, calmness, and resignation. He seemed to say:

> "Bright King of Glory: mighty God!
> My spirit bows before Thy mercy seat:
> To Thee I lift my humble thoughts
> And simply worship at Thy feet."

A Mind-reading Tale.—A certain M. Zamora, of Nantes, who has been giving public exhibitions of hypnotism and mind-reading in that city, has recently turned his canny faculties to practical use, if we may believe an account published in *Le Bulletin Médical* of October 7, 1888. He had been giving an exhibition in the town of Paimbœuf, and it occurred to the authorities of the place to put him to a practical test. There was at that time in the station-house a man accused of the theft of a sum of money from his master, who strenuously denied his guilt, and against whom there was nothing but circumstantial evidence, as the money had not been found upon him or about his effects. M. Zamora, his eyes bandaged, was brought into the presence of the suspected thief and held his hand for a few moments. He then left him and started off at a brisk pace through the streets of Paimbœuf, with which he was not acquainted, until he arrived at a place near the railroad station, where he halted at the base of an old wall, saying that the money was buried there. A little digging soon brought to light a sum of money equal to that lost by the accuser, and composed of pieces of the denomination previously indicated by him. So the story is told. We have not heard whether the accused was convicted on the strength of the evidence furnished by the mind-reader.

Caprices of Nature.—The Surgeon-in Chief at the Maternity, in Brussels, has published the notes of the following two cases: The first was that of a woman, aged twenty-one, a primipara, who continued to menstruate regularly throughout the course of her pregnancy. The second was that of a woman, aged twenty-four, who had never menstruated, but who nevertheless became pregnant and gave birth to a well formed, healthy infant.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 9, 1888, *to December* 15, 1888.

Baxter, Jedediah H., Colonel and Chief Medical Purveyor. By direction of the Secretary of War will proceed to St. Louis, Mo., and Hot Springs, Ark., on public business connected with the Medical Department, on completion thereof to return to his proper station. Par. 13, S. O. 289, A. G. O., Washington, December 12, 1888.

Town, Francis L., Major and Surgeon. Is relieved from duty at the post of San Antonio, Tex., and will report in person to the commanding officer, Presidio of San Francisco, Cal., for duty at that station, relieving Major Henry R. Tilton, surgeon, and by letter to the commanding general, Department of California. Par. 19, S. O. 286, A. G. O., Washington, D. C., December 8, 1888.

Tilton, Major. Upon being relieved by Major Town, will proceed to West Point, N. Y., and report in person to the superintendent of the United States Military Academy for duty at that station, relieving Major Charles F. Heizmann, surgeon. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Heizmann, Major. Upon being relieved by Major Tilton, will proceed to San Antonio, Tex., and report in person to the commanding officer of that post for duty, and by letter to the commanding general, Department of Texas. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Finley, James A., Captain and Assiatant Surgeon. Is relieved from duty at Fort Buford, Dak. Ter., to take effect upon the expiration of his present sick leave of absence, and will report in person to the commanding officer at Fort Assiniboine, Mon., for duty at that post. Par. 19, S. O. 286 A. G. O., Washington, December 18, 1888.

Chapin, Alonzo R., Assistant Surgeon. Leave of absence for fourteen days to commence on or about December 24, 1888, is granted. Par. 1. S. O. 261, Headquarters Division of the Atlantic. Governor's Island, New York City, December 11, 1888.

La Garde, Louis A., Captain and Assistant Surgeon. Leave of absence for one month, with permission to apply for an extension of three months, is granted. Par. 15, S. O. 290, A. G. O., Washington, December 13, 1888.

Jarvis, Nathan S., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War is relieved from duty at Fort Leavenworth, Kan., and will report to commanding officer at Fort Lewis, Col., for duty. Par. 14, S. O. 290, A. G. O., Washington, December 13, 1888.

Johnson, Richard W., Captain and Assistant Surgeon. Is relieved from duty at Fort Adams, R. I., and will report in person to the superintendent of the United States Military Academy, West Point, N. Y., for temporary duty at that station. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 15, 1888.

Penrose, Thomas N., Surgeon. Ordered for examination preliminary to promotion.

Oberly, A. S., Medical Inspector. Ordered before the Retiring Board.

Dickson, S. H., Past Assistant Surgeon. Detached from the Richmond and to the Pensacola.

Ashbridge, Richard, Past Assistant Surgeon. Detached from the St. Louis and to the Richmond.

Auzal, Ernest W., Assistant Surgeon. Promoted to Passed Assistant Surgeon.

Wieber, F. W. F., Assistant Surgeon. Promoted to Passed Assistant Surgeon.

Medical Items.

Contagious Diseases—Weekly Statement. — Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 15, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	21	8
Scarlet fever	210	31
Cerebro-spinal meningitis	1	1
Measles	334	20
Diphtheria	133	23
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

The Happiest of Nations.—It has been said that the happiest nation is that in which the proportion of men and women is most nearly equal, in which the number of illegitimate births is least, which contains the greatest number of healthy adults, in which the average life is longest, and in which the proportion of people beyond sixty years of age is the highest. According to the Paris *Temps*, France is the country in which all these conditions are most fully met. While in Great Britain there are 750,000, and in Germany 1,000,000 more women than men, in France the excess is only 92,000. Between the years 1825 and 1867 the illegitimate births varied in the different countries of the continent from 8.2 to 25 per cent., but in France they were only 7.2 per cent. The mortality in England is 31, in Germany 38, and in France 23.8. The proportion of inhabitants between fifteen and sixty years of age is greater in France than in any other country, and the same favorable showing is made for the average duration of life and for the number of vigorous old people. Nevertheless the population of the country is stationary, or even decreasing, and this in spite of the fact that emigration is small as compared with that from other countries.

Some Popular Medical Superstitions.—In a book entitled "A Bird's-eye View of France in the Middle Ages," M. Challemel refers to a number of superstitions which were current at that time, many of which have not yet died out. There were several means of warding off fevers. One was to eat neither meat nor eggs at Easter and on other solemn festivals; another to carry about on the person a piece of a human bone; and still another to pluck and eat the first daisy found in the field. In order to cure a fever the sufferer would rise early in the morning and go out into the field, walking backward all the time, pluck a handful of herbs, and without looking at it, throw it behind him, and then return quickly to the house. The fever then forsook him and fastened itself upon the devil. The Bretons preserved their children from all evils by putting on them a damp shirt. A knife with a white handle was a sure preservative against colic. The toothache was quickly relieved by touching the painful part with a dead man's tooth. Running here and there, without particular aim, through a church, was sufficient to ward off pleurisy. The formation of gall-stones was rendered impossible by rolling one's self naked in a field of oats. Spitting in the mouth of a live frog was a very efficacious remedy for a cough. Earache was cured by touching the ear with the hand of a skeleton, and headache was quickly relieved by binding the temples with a cord by which some one had been hung.—*Journal de Médecine et de Chirurgie Pratiques*, October, 1888.

"Odium Medicum."—In the course of an address having this title, Dr. L. S. Pilcher (*The Brooklyn Medical Journal*) says: "How little is the spirit of professional enthusiasm which animates the true physician appreciated, or even understood, by the people among whom he works. We hear much of the *odium medicum;* the personal difficulties, jealousies, and rivalries of medical men are exaggerated and commented upon freely; the amiable and sometimes transparent attempts upon the part of ambitious men to secure notoriety and practice are never underestimated; the more striking and positive achievements of particular men are fully acknowledged, and usually greatly distorted and exaggerated by partial friends; but the undercurrent of self-denying enthusiasm, upon which all these men are being equally swept along in their work, is rarely thought of, is doubtless often not even appreciated by the men themselves. But it is this alone which makes their work tolerable. How often do laymen, when they stop to consider even the most ordinary duties of the physician, exclaim in wonder that such duties can be accepted by any man. The tedious waiting by the obstetric bed, and the duties which the culmination of the parturient agony devolve upon the accoucheur; the personal services of the most repulsive character which the surgeon is continually being called upon to render; the often ingratitude of those for whom the most has been done and borne; the responsibility of acts and advice upon which the issues of life depend; the wear and tear of mind and body; these are the things, the enduring of which it may well seem strange that refined and sensitive minds should deliberately undertake. If the spirit of trade alone animated those pursuing such a calling, what grovelling and menial tendencies of mind, what callousness of heart, would it argue in them. But it is not so. The controlling, dominating spirit which sustains a physician in the most trying and in the most undesirable duties of his profession, whether he stops to recognize it or not, is a divinely sent enthusiasm of labor for the relief of men. Nearly all human beings have this feeling in some degree; he who is devoid of it is a moral monster; but in the physician it is cultivated to its highest degree. It is that which sustains him in all his work, and that which is his only solace in many hours of disappointment and misrepresentation."

Dr. Bogdanovski, a well-known surgeon in St. Petersburg, died recently while engaged in an operation. He was about to amputate the arm of a patient, and had already begun the operation, when he was angered by the awkwardness of a student who was assisting him, spoke to him sharply, and suddenly fell fainting to the floor. He soon recovered consciousness and was about to proceed with the operation when he fell again and died in a few minutes. The cause of death was heart-failure.

Cholera Inoculations.—Dr. Gamaleya, a physician of Odessa, has laid claim to the Bréant prize of 200,000 francs for the discovery of a method of preventing cholera. His right to the prize is vehemently disputed, however, by Dr. Ferrán, who maintains that his method of inoculation affords a safe and certain means of preventing the disease.

Ouabaïne is the name given to an alkaloidal substance extracted from a plant growing in Eastern Africa. It is said to resemble strophanthus in its physiological action on animals.

The Universal Language.—The lovers of Volapük are beginning to raise their voices for the adoption of that language by medical societies, especially those of an international character, in order that their proceedings may be understood of all men. They ask now only that the proceedings be printed in parallel columns, one the language of the country and the other Volapük. Why, may we ask, does not some enthusiast establish a Volapük medical journal, *Volapükik medinik gased*, or words to that effect?

One more Effect of Cigarette-Smoking.—Dr. Fenn, of San Diego, Cal., reports a case of dyslalia from cigarette-smoking, occurring in a young miner. The stammering was quickly relieved by abstinence from tobacco and the use of bromides and valerian.—*The Medical Age*, November 10, 1888.

A Physician's Account of Ptomaïne Poisoning from Septic Meat.—Dr. Anderson, of Norfolk, gives the following picturesque account of what a layman would call a bilious attack: "I received into my stomach, while empty, a small morsel of septic meat. In a short time a sickening, sinking sensation was experienced, with copious secretion of hot frothy mucus, swimming in the head, and great nervous prostration. Placed under circumstances which rendered it impossible to use emetics or any other medicaments, I rode for fifteen miles in great torture. Procuring a draught of fine domestic wine, I was enabled to complete my ride, reaching home late at night, after a ride of more than twenty miles, since eating the poisoned meat. Not having eaten anything since early morning, I ate supper and retired. My night was one of great trouble, oppression, and anxiety—frightful dreams tormenting me through all its dreary hours. I arose next morning, weak, sick, tremulous, feeble, and with a frightful vertigo. I ate a light breakfast and hastened to visit some ill patients. I returned about midday, with a sense of sinking which seemed to me to be the prelude to death. I drank a large draught of water and soda, threw up a quantity of nauseating, foaming fluid, and felt as if every support were gone, and I could survive but a few moments. Seeing a mixture of salicylic acid and bicarb. soda on the mantel, I called for it and took a dose, repeating it every fifteen minutes. I distinctly felt it pervade my whole economy, giving force to the heart, clearing up the brain, throwing off the incubus, and affording the most delightful relief. It soon began to operate on my kidneys, and a very copious flow of urine followed. It was evident the medicine had neutralized the septic agent and caused its rapid discharge by the kidneys. Here was a ptomaine, exceedingly minute, which in twenty hours had so transformed and poisoned all the fluids as to place me in imminent peril."—*The American Lancet*.

The Heredity of the Morphine Habit.—Erlenmeyer says that children born of women addicted to the morphine habit are practically morphine-eaters at birth. During the first few days of life, unless morphine is given to them, they are very apt to suffer collapse, and this condition may end in death, the child being too weak to withstand the violent symptoms which are similar to those which follow the sudden withdrawal of the drug in adult opium *habitués*.

Hayap, a New Local Anæsthetic.—At a recent meeting of the Berlin Medical Society, a substance brought from Africa, and known there by the name of hayap, was presented as a local anæsthetic of considerable power. The substance is in the form of a reddish mass. An aqueous solution instilled into the eye of an animal caused, within fifteen minutes, complete anæsthesia, which was maintained in several instances for from ten to twenty-four hours. The roughest treatment of the conjunctiva gave rise to no evidences of pain on the part of the animal.

The Value of Medicine.—A contemporary, in an obituary notice of Dr. David Robinson, an eccentric physician, of Paterson, N. J., says: "He was fond of trying medicines on himself before giving them to his patients, which practice caused him much suffering and ill-health."

Different Therapeutic Methods.—In a paper entitled "Therapeutic Nihilism" (*The Boston Medical and Surgical Journal*) Dr. M. Clarke speaks as follows in regard to therapeutic methods: Some men are naturally disposed to look at disease from the stand-point of preventive medicine; some from that of hygiene; some with a reverence for the *vis medicatrix naturæ*; some with a belief in active medication. The latter position is certainly the most attractive to the average medical man, and, in the presence of any serious illness, it is the most acceptable to the laity, in spite of the popularity of that therapeutic *opéra bouffe*, homœopathy. Again, some men incline to run after new fashions, treating all diseases impartially and indefatigably with the newest discoverable drugs, and endeavoring to keep up with the samples of the manufacturing chemist; this is the experimental therapeutist. Others, too inert perhaps to shift for themselves, leave to these the practice of experiment, but borrow from them the suggestions their results afford; this may be called vicarious therapeutics. Others, again, settle back into the comfortable habit of always giving the same thing for the same disease, and thus, having once been in travail and delivered of a diagnosis, have nothing left to do but consult their books or their memories for the indicated remedy; this method of practice, I suppose by far the most common and certainly the most degrading of all, is routine therapeutics. There are a few physicians, however, who look upon each case as to a certain extent *sui generis*, and who bring to its relief not only the results of the experience of the past and the experiments of the present, but also a personal opinion of the needs of a particular case, and who, so far as they are allowed, endeavor to do what a sound training, an impartial judgment, and an active conscience command, and this seems to me rational therapeutics.

Statistics of Medical Students in Paris.—The statistics of the Paris Faculty of Medicine, published for the year 1887–88, show 373 graduates, of whom 321 were French. Fifty were foreigners and two were women. One of the latter was a French subject, Mme. Sollier, a colored lady of Martinique origin, and the other was a Roumanian lady. The list of male graduates comprises those of all nationalities. Thirty-six were Russians. Americans stand next in order of numbers, but almost all of them were Spanish students from the South American States; only one was from the United States. At present the number of students enrolled on the books of the faculty is 3,782. Of these 114 are women. Only one of them comes from the United States, and only two men come from there. Twelve of the women are French, 90 are Russian, and there are a few English, Greeks, and Austrians. The male foreigners number more than 560, including 140 Russians and Poles, 130 Spaniards and Spanish Americans, 19 Greeks, 56 Turks, and the others from various European states, there being 34 Englishmen.—*New York Medical Journal*.

Electro-therapeutics Run Mad.—A Texas physician writes to the *Kansas Medical Index*, that he is using electricity in typhoid fever, and finds that it is antipyretic and antiphlogistic, and superior to any other agent he ever used.

The Bacteria of Sea-phosphorescence.—Professors Pflüger and Tilanus have discovered the bacteria that produce the phosphorescence of sea-fish, and have cultivated them by Koch's method. In the dark the glass slide containing them is seen to be thickly strewn with luminous points.

Senile Rheumatic Gout.—Dr. William Bruce contends that there is a class or kind of acute senile arthritis which belongs to a different category from gout and rheumatism on the one hand, and rheumatoid arthritis on the other, and is remarkable in its severity and complete curability, even at a very advanced time of life. The following are notes of a case of this form of disease: An inn-keeper of seventy, imbibing stimulants rather freely but enjoying very good health, had complained of some "rheumatic" pains for a day or two. He was then exposed to cold and wet for some hours, came home very ill, and took to bed. He became completely crippled with "rheumatic gout," affecting his hands and feet as well as his wrists and ankles. He was treated with salicylates, alkalies, and iodide of potassium, which gave relief, but when he arrived at Strathpeffer, three months after his first seizure, he was completely helpless, and could not even turn himself in bed, or feed or dress himself. He took the sulphur waters internally, had frequent baths, and thorough massage. He was perfectly cured, and left Strathpeffer, walking about briskly, in three weeks. Next year he returned, but was merely suffering from slight twinges, and had been particularly well since his first visit. He had never had any urinary trouble, and there is no rheumatic history in his family. The jaws were not affected. The whole aspect of his case leaned to the side of polyarticular gout, and yet the obstinacy of the attack, his age and history, point more to rheumatoid arthritis.—*The Practitioner*, November, 1888.

Hare-lip and Maternal Impression.—Dr. E. H. Wakelee, of Big Flats, N. Y., writes: "On November 16, 1888, I was called to attend Mrs. N——, in her fourth confinement. She was successfully delivered of a male child which had a double hare-lip, with cleft palate of the right side. Her first child (a girl) had a single hare-lip, which was operated upon about May 1, 1888, by Dr. Henry Flood, of Elmira. The mother was present at the time, and says the sight of the blood, cries of the child, and other details of the operation disturbed her very much. During the remaining period of her gestation the mother, to use her own words, 'worried continually for fear the child would be marked.' On inquiring carefully into the family history I found, with the exception of the sister above referred to, no one in the family, for generations back, had anything of the kind. Was the deformity due to maternal impression?"

Rickets and the Weather.—Dr. Rudolf Fischl, of Munich, has been studying the influence of the season upon rachitis, and states that the severest cases begin about New Year, while from April to October, when the children are much in the open air, and even the poorest can ventilate their houses by opening the windows, the frequency of the disease diminishes. This favorable influence of fresh air is felt up to the end of the year. The decrease in rickets during the summer is due also to the fact that many mild cases, which never come under the physician's eye are cured spontaneously at this season. The greater number of cases of rickets are seen in the Munich clinic in May, November being the month in which the smallest number of cases present themselves. —*Deutsche Medizinal Zeitung*, November 5, 1888.

Counter-prescribing is said to be the rule rather than the exception in Kansas City, no one thinking of calling on a physician unless he finds himself seriously ill. As a retaliatory measure, many physicians are dispensing their own medicines.

The Constant Presence of Spirilla in a Case of Relapsing Fever.—Hitherto it has always been found that Obermeier's spirochetæ were present during the fever, but absent in the internals in relapsing fever. In a few exceptional cases the spirilla have been found at periods varying from two to twenty-four hours after defervescence had occurred. Dr. B. Naunyn reports a case, however, occurring in a man, fifty years of age, and terminating fatally in the sixth week, in which the spirochetæ were present in the blood constantly for a period of two weeks. They were more numerous during the height of the fever, and scarce during the intervals, but never disappeared entirely, even in the absence of all fever.—*La Riforma Medica*, November 7, 1888.

Ear Disease and Rickets.—Dr. Eitelberg has found, in aural examinations made on one hundred rachitic children, pathological changes in the drum-membrane in over ninety per cent., while in healthy children such changes were found in only a small proportion of cases. On account of the softened condition of the temporal bones in rachitic children, the author believes that diseases of the ear are likely to be much more serious in their consequences in them than in healthy children.—*Deutsche Medizinal Zeitung*, November 5, 1888.

False Cinchona.—In some parts of Bolivia and in the Northern provinces of the Argentine Republic there is found a tree, the *Cascarilla morada*, the bark of which is reputed to possess therapeutical properties identical with those of cinchona. Drs. Arata and Canzoneri have recently examined this bark (*Revista Argentina de Ciencias Médicas*, November 5, 1888), and have extracted from it two principles which they call *moradina* and *moradeina*. The former occurs as fine colorless needles or coarser prisms, which, after exposure for some time to the air, acquire a pale-yellow tint. It possesses the properties of an acid, the solution reddening litmus-paper, but does not form stable compounds with alkalies. Moradeina is an alkaloid, very slightly soluble in water but freely soluble in alcohol, ether, and chloroform. The hydrochlorate crystallizes in the form of a mass of interlacing needles.

A Curious Verdict.—A young woman in Lancashire died while under the influence of chloroform administered before the extraction of teeth. The jury returned a verdict of "death from misadventure."

Ptomaïnes and Gastric Vertigo.—Vertigo a stomacho læso is the result, according to M. Gaube and others, of autochthonous poisoning, the poison being a base belonging to the group of cadaveric alkaloids or the ptomaïnes of M. Gautier. The fæces and the urine of individuals suffering from digestive derangements accompanied by dilatation of the stomach contain the poison. The dilatation may be a symptom of the presence of the poison, which is an uncrystallizable base having alkaloidal qualities, and forming soluble crystalline salts with muriatic acid. It is absorbed into the circulation, and determines giddiness by its effect on the brain, just as is imagined to be the case in uræmia. Injected under the skin of young rabbits, half a milligramme of the hydrochlorate of this ptomaïne caused coldness of the ears, extremities, and surface of the body within the first hour, and much urine was passed; in twelve hours appetite was lost, the fæces became soft, and the urine scanty; death occurred in from thirty to thirty-six hours after the injection, the head of the animal being held in such a manner as to suggest giddiness.—*The Lancet*, November 3, 1888.

Double Placenta with Single Pregnancy.—At a recent meeting of the Paris Academy of Medicine, Dr. Guéniot exhibited a double placenta which he found in a case of single pregnancy. Each placenta represented the volume of that of a pregnancy of seven or eight months. The umbilical cord, at first apparently single, was divided into two cords just before reaching the placenta, the blood-vessels being apportioned between them. There are only a few examples of this kind recorded in obstetrical works, which may have very grave importance from a medico-legal point of view: for instance, in cases of alleged infanticide, where a woman delivered of only one child with a double placenta might be charged with having had twins, one of which she might be accused of having destroyed.—*The Lancet*.

Saccharin not a Substitute for Sugar.—A report by a Medical Commission, appointed by the Minister of Commerce, to examine into the properties and effects of saccharin as a food, expresses the opinion that materials which are antiseptic or capable of fermentation should not be introduced into food. It should be borne in mind, the report continues, that a substance is only a food on condition of its being able to undergo in the economy all the series of changes which render it assimilable. Not only is saccharin not a food, but by its antiseptic properties it renders entirely unalterable the substances with which it may be mixed. To substitute saccharin for sugar, therefore, is to suppress an article of food in order to replace it by an inert body; it is to check or retard the physiological actions which produce the change into sugar of the amylaceous materials; it is, in short, to expose the organism to a double deficit. The delay effected in the change of the fibrin of the albumen is not clearly shown. Hence the commission concludes that saccharin should not be introduced into food; that it is not a food and cannot replace sugar; that its use, or that of its preparations, seriously disturbs the digestive functions and increases the affections known under the name of dyspepsia, and that it should be prohibited as an article of food. It is said that the Portuguese Government has prohibited the introduction of saccharin into that country.—*British Medical Journal.*

Unsuccessful Inoculations in Rabies.—A patient, bitten by a mad cat on June 16th, was treated at Pasteur's Institute from June 20th to July 7th. The course of inoculations having been completed, he was discharged and returned to work. He died with the characteristic symptoms of hydrophobia on July 18th.—*Polyclinic.*

Anæsthetics in Labor.—The ethical question, How far is it pusillanimous and even irreligious to profit by the annihilation of pain which anæsthesia affords under surgical operation, and in parturition? has recently undergone discussion anew in some of the French papers. The discussion is antiquated and out of date in this country, and many of the stories told would hardly bear repetition in this serious country. Sir James Simpson long ago disposed of the argument now revivified, which charges the woman who accepts anæsthesia in childbirth with evading the biblical injunction of pain. An indignant Frenchwoman has revived an old argument with some flippancy, but not without a reckless wit. "You quote," she says, "some verses of the Bible against us; but let me remind you that the only one of your sex who took his part in the act of giving birth profited by anæsthesia; for when Adam gave up a rib toward the creation of Eve, he was first thrown into the deep sleep of insensibility."—*British Medical Journal.*

The Smell of Meat.—The examination of the flesh of animals from which the viscera have been removed necessitates the analysis of all the tissues, the inspection of the fat, muscular tissue, fasciæ, pleura, and peritoneum, spinal cord, glands, vessels, blood, etc., before the meat can be accepted. In the normal state the flesh of every animal has its own characteristic odor. Beef has a special, insipid kind of smell, modified by the different modes in which the animals have been fed. Thus it is stated that the flesh and milk of cattle in the polar regions have a fishy odor, because the absence of pasturage obliges the inhabitants to feed their oxen and cows on fish. Veal smells of milk, mutton of wool and sometimes grease. The normal odor of pork is insipid and inoffensive, but when the pigs are fed on offal the flesh has a pale cachectic hue, and an offensive smell and taste. The odor of poultry fed on corn differs from that of poultry artificially fattened. In a diseased state, meat emits a typical odor resembling the breath of feverish patients. This odor is particularly noticeable beneath the shoulder and in the muscles of the inner side of the leg. The odor should be carefully noted immediately after the incision is made. This should be done by the inspector himself. When diseased meat is roasted it emits a strong and offensive smell. The fever odor is particularly marked in the case of animals which have suffered from peritonitis, charbon, morbid symptoms following parturition, or with ordinary acute disease. In such cases the smell is recognizable at once, and it is unnecessary to make any incision. "Feverish" meat is always unfit for consumption, on account of the leucomaines which it may contain. Moreover, there always exist pathological lesions which denote clearly that the animal was diseased before being killed.—Paris Correspondence of *The British Medical Journal.*

The Sex of Infants.—Dr. Dupuy advances a new theory concerning the sex of infants, which is, according to him, merely a question of mathematics. If the first child has been conceived in a certain menstrual period, which may be called No. 1, all the subsequent children conceived in the odd periods, such as the 25th, 61st, etc., will be of the same sex, while those of the even periods. 24th, 60th, etc., will be of the opposite sex. The mathematician seems, however, to be the male parent, for if the father dies and the woman marries again, the series begins over again, according to the author, and the count must begin with the first child of the new union.

Dangers of Blistering in Cardiac Disease.—Professor Jaccoud, of Paris, calls the special attention of practitioners to the contra-indications to the employment of flying blisters in certain cases of disease of the heart. The important point, according to this distinguished authority, is to ascertain the state of the kidneys in these subjects. In case there be discovered in the urine even the smallest trace of albumen, the use of blisters to the præcordium ought to be rigorously proscribed. Neglect of this rule has led to the unwitting aggravation of the patient in many instances. Sometimes ignorance has been the cause, sometimes imperfect testing, at other times culpable temerity—which has made light of the presence of albumen while a blister was being prescribed. It is easy to substitute iodine paint to the præcordium if cantharides be contra-indicated.—*The Practitioner*, November, 1888.

The Hour of Death.—It has been said that the greatest number of deaths occur between four and six o'clock in the morning. As a matter of curiosity, and to ascertain whether there is any truth in this statement, Dr. Charles Féré has tabulated the hour of death of all the patients dying in two of the hospitals in Paris for the past ten years. He found that there was no preponderance of mortality at any particular hour, although there were somewhat fewer deaths between seven and eleven o'clock in the evening than at other periods of the day.

Medical Men in England.—According to a recent report of the General Medical Council, the number of physicians and surgeons in England is constantly increasing. In 1881 the proportion was 1 to 1,747 inhabitants, and in 1887 it had risen to 1 in 1,662. In Salford there is 1 physician to 977 inhabitants, in London, 1 to 929, and in Brighton, 1 to 727.

Diabetes and Malaria.—At a recent meeting of the Paris Academy of Medicine, M. Mossé read a paper in which he made the assertion a temporary glycosuria of no practical importance was occasionally seen in those suffering from malarial affections. To this statement M. Verneuil took exception, and cited a number of observations made by practitioners in the East, showing that diabetes mellitus was a very frequent and serious sequel of malarial infection. In countries where hepatitis is endemic, he said, an attack of intermittent fever was very frequently followed by permanent glycosuria.

In France the average life of a generation is but 31 years, and the number of infertile marriages is thirty-four out of a hundred.

Dysmenorrhœa.—Dr. J. Shaw recommends, in *The Lancet* of September 22, 1888, a mixture of belladonna and hyoscyamus for the relief of dysmenorrhœa. It is particularly in the so-called neuralgic or spasmodic form of the affection that this mixture seems to afford the greatest amount of relief.

Female Drug Clerks in Russia.—A recent imperial ukase authorizes Russian women to practise pharmacy, provided that they have obtained a diploma. Pharmacists who have young men as clerks are forbidden, however, to have any female clerks or students. The Czar's government is nothing if not paternal.

Restricting the Sale of Diplomas.—According to a recent order of the Minister of the Interior of the Ottoman Empire, upon the death of a physician or pharmacist, the diploma of the deceased must be returned to the college which granted it. This decree was rendered necessary by the fact that many quacks had bought the diplomas of deceased physicians and were practising on the strength of the authority so obtained.

The First Insane Asylum in Greece has been recently established in Attica. Hitherto the insane in that country have been cared for in the convents.

Suicides in the Italian Army.—In the Italian army, between the years 1874 and 1880, the number of suicides rose from 40 to 110, or from 20 to 52 in 100,000, but from 1881 to 1886 the number decreased to 50, or 24 in 100,000 soldiers. The ratio of suicides in the army to those in civil life varied during this period from 4 to 1 to 2 to 1.

The International Society for the Prevention of the Defilement of Rivers held its annual meeting in Cologne on September 17th, the day preceding the meeting of the Society of German Naturalists and Physicians. The preservation of the purity of the soil and air is equally, with the object expressed in its name, an aim of the Society.

Ice-cream Poisoning.—Dr. C. N. Jones sends an account of the poisoning of a social party by ice-cream. In seeking for an explanation of the occurrence he found that the freezer was made of tin and was soldered on the inside. To cause the solder to adhere to the tin the tinsmith used zinc and muriatic acid. The writer asks whether the presence of the acid and zinc may not be the cause of poisoning in many cases of this nature, especially where particular care has not been taken to thoroughly rinse out the freezer with hot water before using.

A CHRISTMAS-EVE DISASTER.

By GOUVERNEUR M. SMITH, M.D

Good Santa Claus, in happy glee,
One Christmas-eve, his jubilee,
Set out the world to oversee,
With agile deer;
Loaded as he, and only he,
Knew how to cheer.

The night half gone, when stockings still,
Both near and far, were yet to fill,
A homestead old, on lofty hill,
Now met his sight;
He dash'd with will, and reach'd with skill,
The chimney's height.

Bricks loose and dry, and smoky stuff,
Made journeying slow, and footing rough,
But down he hied, without rebuff,
He knew the way,
For years he'd found, same chimney tough;
Duty was play!

He tripped his toe, and down he fell,
'Mid dust and stones, a sad pell-mell,
Ah! sorry plight, and hard to tell,
Gray hairs were red;
His head though cut, limbs torn as well,
No tears he shed.

The inmates woke, most dead with fright,
The babe had fits, the dog showed fight,
The snarling cat sought peace in flight,
Striving to scratch;
Such chimney spright, at dead of night,
Had had no match.

Brave Santa spoke, his words were frank,
"Your friend am I, not mountebank,
St. Nicholas, I churchly rank.
'Tis not a spree,
Nor drunken prank, though torn and lark,
As you may see.

"Void stockings hang, by mantel side,
O'er half the earth, and 'tis my pride,
All, all to fill, for each provide:
I must away,
Or friends will chide, and laughter hide,
On Christmas-day."

Though rather shy, they all agreed,
'Twas kindly act, their guest to speed,
To dress his wounds, not let him bleed:
So one and all,
Began good deed, in his sore need,
On friendly call.

A doctor young, of sprightly mien,
On visit home, in Physic, green,
Hearing the noise had joined the scene,
And played a part;
Now, calm, serene, with wits all keen,
He tried his art.

Bichloride wash, he made with care,
Bacterial germs, might lay a snare,
To operate, he would not dare,
(With Lister's skill),
'Till he could swear no microbes there
A Saint to kill.

He stitched his brow, his cheek, his lip,
Plastered his nose, with good broad strip,
Placed on his ear, a caustic tip,
Working with will,
Sewing each rip, for his cold trip,
With gentle skill.

Splintered one leg, and oiled each limb,
Elbow reset, put hair in trim:—
With all good care, he still was slim,
But full of vim,
Words were not grim, heart full to brim,
Of Christmas hymn.

Santa to each, gave thanks with mirth,
"Stockings are full, no Christmas dearth,
I wish you joy, in Heaven, on earth,
God bless your speed,
Both old and young, seek saintly birth,
And learn my creed."

Though weak and limp, he dashed with zeal,
Scarce half night left, to scatter weal,
And did his work, with jingling peal,
'Till his eve's close,
Reaching his home, in time to kneel,
As sun arose.

The Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 34, No. 26 NEW YORK, DECEMBER 29, 1888 **Whole No. 947**

Original Articles.

WAS IT METASTATIC RHEUMATIC PERITONITIS?

BY CHARLES W. PACKARD, M.D.,

NEW YORK.

WITHOUT entering upon the disputed question as to whether or not there is such a condition as idiopathic peritonitis, I present the following history of a case that, during part of its course, seemed to compel a diagnosis of peritonitis from some unexplained cause, and to fairly raise the question of the expediency of an explorative laparotomy:

On the evening of November 19th I was called to see R. B——, a boy, twelve years of age, who had for two days been suffering from severe abdominal pain, with frequent vomiting, that the usual household remedies had failed to relieve. I learned that for several years he had been subject to occasional attacks of chorea of a mild grade, for which arsenic had been given him, and that at the time of his present seizure he had been taking ten drops of Fowler's solution three times a day. At first it was thought possible that his condition might be due to arsenical poisoning, but this view was dispelled in the after-history of the case. The existence of former rheumatism was denied, although subsequent inquiries revealed the fact that he had often complained of lameness after play, and of such tenderness in the soles of his feet as to make him limp in walking. He had been to school as usual on Monday, November 19th, but on coming home was taken with a chill, followed by vomiting and severe pain in the right iliac region, that soon became general over the whole abdomen, although as the focal point of the pain he constantly referred to the right iliac region throughout the course of his disease. There had been three loose movements of the bowels on that day, and a daily natural movement for several preceding days. Upon examination the abdomen was found retracted and of board-like hardness, the recti muscles standing out tense and prominent, and the whole abdomen so sensitive to touch that only the most superficial percussion and palpation could be attempted. There was an equal resonance on light percussion over the whole abdomen, while the muscular tension seemed greater over the right iliac region than elsewhere. The decubitus was dorsal; the knees drawn up; respiration thoracic, shallow, and thirty in the minute. Temperature 102°, pulse 120. The stomach instantly rejected food or drink, and even fragments of pounded ice were as often vomited as retained. Urine about normal in amount, and passed without pain. The tongue was coated, expression of face anxious. There was a slight systolic endocardiac murmur, to account for which I could get no history of antecedent rheumatism. Ordered suppositories of morphine and belladonna, and to apply oiled silk and cotton wadding sprinkled with ol. turpentine to abdomen.

November 22d.—The general condition of the patient is about the same, except that the pain has lessened under the influence of the morphine. Patient has had no sleep. The abdomen remains hard, and is beginning to swell. The stomach retains nothing, but the vomiting is less frequent, and nothing is brought up but a mouthful or two of colorless and watery mucus that seems to be regurgitated rather than vomited. The pain is still constant, and severe in paroxysms, which are at times accompanied by expulsion of a little flatus. Bowels not moved. Temperature 101½°, pulse 118, respiration 34 in the minute.

To take ten grains quinine in suppository, in addition to morphine and belladonna before ordered.

November 23d.—Passed another sleepless night. Tympanites much increased. Liver dulness pushed up. Stomach rejects everything, and there is still occasional vomiting of colorless mucus. Temperature 101° F., pulse 118, respiration 38.

November 24th, morning.—Symptoms unchanged. A little milk and lime-water has been retained. Bowels moved, motion formed, and passed with flatus. About a pint of high-colored urine passed during last twenty-four hours, and without pain. Still no sleep. Temperature 102½° F., pulse 116, respiration 40.

November 24th, evening.—Aspect of patient is worse. Tympanites increased. Skin of abdomen shining and tense, and showing enlarged veins. As patient lies on his back, the level of abdominal wall is crowned up considerably above the chest level. The respiration is shallow, costal, and forty in the minute. Pulse 130, temperature 103½° F. Abdominal pain is general, but greatest in right iliac region, which he guards against any touch. He has for several days past been taking morphine, ⅙ grain, with belladonna, ⅛ grain, in suppository, every two or three hours, as the pain might indicate, and this amount has kept the pupils moderately contracted and the pain within tolerable limits, but he has had no sleep. Ordered morphine to be increased to ¼ grain, to be used as before.

Up to this point the case has presented some favorable aspects. The occasional movement of the bowels; the passing of flatus; the free secretion of urine; the absence of green vomit, and of signs of profound nervous shock, such as we expect to find in peritonitis resulting from perforations. The pulse, too, has shown less tension than is usual in this disease.

On the other hand, there is a distinct history of chill, followed by severe and persistent pain in a most suspicious locality—especially in a child—and rapidly spreading from this point until the whole peritoneal area is involved; persistent vomiting and fever, steadily increasing tympanites, going on until the belly has reached a high stage of distention; and now, after five days of this history, there comes a decided increase in the temperature, the pulse grows more frequent, the face more anxious, and the general expression of the disease decidedly worse.

Thus far the tenderness and rigidity of the abdominal wall have been so great as to render deep percussion or palpation impossible, and it has not been determined whether there is a small typhlitic tumor or not. Considering the history of the case, it seems not unlikely that the inflammatory process now going on began as a typhlitis, and the patient's condition is evidently going "from bad to worse."

Is there peritonitis? and if so, is the patient's condition such as to justify an explorative laparotomy?

The first question could be answered in the affirmative with little hesitation, but it was deemed safer for the patient to take the possible risk of waiting too long, rather than to invoke the certain danger involved in the surgical operation. The question of operation was therefore postponed.

November 25th.—An early visit found the boy complainr ing bitterly of pain in the *knee-joints*, which during the night had become inflamed with acute rheumatism. The pain in the belly had disappeared so far as to give him no trouble unless he moved, vomiting had stopped, the countenance was better, and the whole aspect of the case had changed as if by magic. The slight heart murmur heard at my first visit had become much intensified by a fresh endocarditis.

Under the administration of salicylate of soda the new rheumatic symptoms quickly disappeared, and in a few days the boy felt well enough to leave his room.

Within twenty-four hours after the metastasis from the abdomen to the joints and heart, the tympanites had largely abated, and the abdomen had become so tolerant of pressure, and so relaxed, that for the first time it was possible to make a thorough exploration. There was no typhlitic tumor, and no fluid discoverable in the peritoneal cavity. From the rapid disappearance of all symptoms, it would seem doubtful if there was an exudate of any kind upon the peritoneum, such, for instance, as we find in rheumatic pericarditis.

I have been unable to find any description of the pathological changes to be found in rheumatic peritonitis, perhaps because there are no fatal cases; and yet the rheumatic poison so constantly elects tissues analogous in structure to the peritoneum, and at times works so great havoc among them, as in pericarditis, that it would seem possible enough to meet with a purely rheumatic and fatal peritonitis.

ERGOT IN OBSTETRIC PRACTICE.[1]

By J. T. DEEMER, M.D.,

KITTANNING, PA.

At the last meeting of our Society I propounded some questions in regard to the use of ergot in labor. I recited the following cases from my practice:

Case I.—Multipara. I had confined her in a previous labor, which was normal, but in this case she had every indication of uterine inertia; the parts were all dilated and membranes ruptured, and instruments being objected to, I gave ergot in what I considered safe doses. The pains increased, became continuous, and the child was born, but it was dead, although I had every reason to believe it had been living until the pains became violent. The mother insisted on having ergot, as she, being an Englishwoman, claimed the English doctors always gave it, and I understood she had a number of still-born children by ergot under the same circumstances. I could find no other reason then, and I can see no other reason to-day, for the death of that child than ergot.

Case II.—This case was almost identical with the first case. The pelvis was roomy; multipara; everything dilated, but the pains were insufficient. I gave ergot, the pains became strong and continuous, and the child was soon delivered, but life seemed extinct; but by persistent effort, inversion, friction, hot and cold water, and inflating the lungs the child revived.

Case III.—This case was seen in consultation and was much the same.

In regard to how ergot causes death to the child, I will endeavor to show that it is in two ways:

1. The more probable is by disturbing the placental circulation, or by cutting off uterine oxidation of the fœtal blood; and another, or 2, is by the action of the ergot on the fœtal heart. The first I consider the most tenable. I will now cite some authorities that I have examined on the subject of ergot in obstetric practice, and we will see what may be said for and against its use, and I feel certain that the weight of evidence is against its use in every case as a means of delivery.

Bartholow says that it is no longer a matter of doubt that ergot produces uterine contractions; that it originates them without previous effort of the womb is questionable. The contractions due to ergot differ from the spontaneous natural contractions in being less rhythmical and more tetanic. When large doses of ergot are used a continuous expulsive effort may be produced. He says ergot is indicated in labor when there is uterine inertia, the first stage being completed and no obstruction existing at the outlet. If given before dilatation is completed, the perineum rigid, and the ostium vaginæ not relaxed, disastrous consequences may ensue to both mother and child. On the part of the mother, the violent and continuous pains, with the resistance in front, may cause rupture of the womb or laceration of the perineum. On the part of the child hæmatosis, partly by direct action on the placental blood, and partly by the continuous compression of the body, but the chief danger is paralysis of the fœtal heart.

Playfair says: "There can be no doubt that ergot causes uterine contractions. The risk to the child is, however, quite as great as when the membranes are punctured; for not only is it subject to injurious pressure from the tumultuous and irregular contractions which the ergot produces, but the drug itself, when given in large doses, seems to produce a poisonous influence on the fœtus."

For these reasons ergot may properly be excluded from the available means of inducing labor. He also says ergot stimulates uterine pains powerfully, and says it cuts off the fœtal circulation. In Dublin, in the Bethesda Hospital, the use of ergot has been prohibited by the trustees.

Ramsbotham at one time advocated ergot, but finally dropped it as a means of inducing abortion.

Professor H. C. Wood: "Ergot was at first called the pulvis parturiens, from the fact of its being able to intensify labor pains." He says: "If ergot be given in small doses during labor, the pains are simply intensified; but if the dose be large enough the character of the pains becomes much altered, *i.e.*, they become long and continuous. The danger to the mother is twofold: rupture of the uterus and laceration of the perineum. Rupture of uterus from this cause is not often met with. The danger to the child is cutting off the placental circulation, thereby not allowing the fœtal blood to be properly aerated, for the fœtal blood is oxygenated during the interim of uterine pains. The child soon dies if delivery does not take place soon after the administration of large doses of ergot, when the pains have become severe." He adds: "Never give ergot in uterine inertia unless there is no resistance. Even under the most favorable conditions ergot should be used with caution. Instrumental delivery is better, if used skilfully."

After all that can be said for ergot, and the much that can be said against it, is it justifiable for the obstetrician to resort to ergot as a means of promoting the delivery of the child? May not what is considered a small and safe dose act with frightful effect? May we not have some obstruction from some fault after the head has engaged, which before we were unable to see? How many of us, when there seemed to be no obstruction to delivery, and when we have assured the woman and her friends that she would soon be delivered, have had to wait, be disappointed, disappoint the woman and all who are interested in her welfare, and then had to extract the head, which had unexpectedly impinged on the bony outlet. I have suffered such humiliation, but I have in all cases come to consider instrumental delivery preferable to ergot. I am not in favor of using forceps until we have given nature a fair chance, for by a little time, change in position of the woman, and if she be much exhausted a little brandy, a binder, and some rotating of the fœtal head if needed, and by encouragement, which of itself is a great stimulant, we may facilitate to a natural termination a tedious labor in which we had about concluded to resort to instrumental delivery.

The uses of ergot after delivery are important. Some good obstetricians recommend a dose to be given just when the head is emerging in every case, but the more conservative recommend a dose only in cases where we are to fear post-partum hemorrhage from the previous history of the case.

---

[1] Read before the Armstrong (Pa.) County Medical Society, November 27, 1888.

I almost concur in the opinion of Professor T. G. Thomas, of New York, that labor is, as a rule, and in the great majority of cases, a normal physiological process and requires no treatment whatever by drugs.

In a case where I feared post-partum hemorrhage I would use ergot in every case, and if a previous history of post-partum hemorrhage existed I would anticipate by giving ergot as the head emerged from the vagina. I have never seen a case of post-partum hemorrhage that demanded ergot hypodermically.

The use of ergot is recommended by Playfair to diminish after-pains. The action of the ergot in expelling the coagula must be the *mode medendi.*

I have thought ergot indicated after tedious labors, and if such cases are observed I think it will be seen that they are likely to be troubled with after-pains and coagular gathering in the uterus, and ergot, by stimulating the contractions, is very beneficial in all such cases. In cases of subinvolution there can be no question of the efficacy of ergot combined with the bromides, and if we conclude to abandon ergot as dangerous before labor, let us consider it an invaluable drug in the hands of the obstetrician to promote the welfare of the woman in certain cases after delivery.

A CASE OF DYSPHAGIA WITH DILATATION OF THE ŒSOPHAGUS.[1]

By MAX EINHORN, M.D.,

NEW YORK.

I TAKE the liberty of presenting a case of dysphagia combined with dilatation of the œsophagus. Œsophageal dilatations may be divided into two groups:

1. Those in which the dilatation originates from a stenosis, whether this stenosis be caused by a carcinomatous infiltration, a cicatricial stricture, or a tumor growing on the inner wall of the œsophagus and occluding its lumen, or by any external tumors pressing on the œsophagus.

2. Those in which no material stenosis of the œsophagus can be found.

This latter group includes the cases very seldom met with. There are only seventeen cases mentioned in the literature,[2] nearly all of which were recognized and described only at the autopsy. Until lately they have generally been considered as cases of primary dilatation of the œsophagus.

In the beginning of this year Meltzer,[3] for the first time, published a case of dysphagia with dilatation of the œsophagus during the life of the patient. There was no anatomical stenosis present. The cause of the dysphagia in his patient was attributed by Meltzer to the existence of a spastic contraction of the cardia, which, in his opinion, resulted in dilatation of the œsophagus. Meltzer doubts the existence of a primary dilatation of the œsophagus, and thinks that most of the cases described must have been due to some other cause, as, for instance, spastic contraction of the cardia.

My case, likewise, may be classed in the group of dilatation of the œsophagus, without any anatomical stenosis. Hitherto it would have been classified as primary dilatation of the œsophagus, but, like Meltzer, I am inclined to look upon the dilatation in my case only as a consequence of some other primary disturbance.

Before entering deeper into the subject I will present a full history of the patient.

J. W——, forty-five years of age, janitor, had typhoid fever twenty-five years ago, since which time he has enjoyed perfect health. In the beginning of March, this year, the patient fell down in the street, striking his back against a small projection. He arose unaided, and resumed his work without any annoyance. On the following day he had a pain in the upper part of the body, especially in his arms; this lasted but a few days and disappeared.

About fourteen days later the patient began to have a feeling of fulness after eating, and had a pressing sensation above the regio gastrica. Two or three weeks later he noticed some difficulty in taking his food, and tried to assist it by drinking warm water several times during the meal; only in this way did he succeed in enjoying a whole meal.

In May, on account of this pressing sensation, the patient was compelled to leave the table in the middle of a meal and walk up and down the room, making deep inspirations and expirations; he used to press with his hands upon the front of the lower part of his thorax after having made a deep inspiration and closed the glottis. The patient says that these attacks during a meal resembled very much a suffocating condition. The described manipulation usually brought him relief, allowing him to eat again, but then the process repeated itself. In the morning he could eat more easily than at noon-time.

Since June last the patient has been sleeping very badly (at most three hours during the night). When in bed he had often a sensation as if something would go up and down in the interior of his chest, and when this sensation came on he was forced to cough quite often. From time to time it happened that he awoke, his mouth being full of fluid; also while awake some fluid at times came up into his throat and mouth, this only happening when in the recumbent position. When standing, he was never compelled to empty his throat.

The patient became thin, felt weak and miserable, and soon could partake only of fluids. The sight of solid food enraged him to such a degree that he threw it away with disgust. Even fluid substances were taken only with great difficulty; he used to throw his arms backward, and, standing straight, his head leaning toward the back, after a deep inspiration and with closed glottis he pressed firmly. The condition of the patient became worse and worse; he lost forty-one pounds during these few months, and went for aid to the German Dispensary on October 23, 1888. *Status præsens*, October 23, 1888: Patient tall in stature and lean; looks pale. The integument can be lifted in large folds. The physical examination of the thorax and the abdomen cannot detect anything abnormal. The heart-sounds are normal. Pulse, 70; respiration, 20; temperature, judging from sensation upon the chest, not increased. The patellar reflex is present, and the patient is able to stand with eyes closed. The urine does not contain any sugar or albumen. The patient complains of not being able to eat any solid food, and of difficulty in taking even fluids, as he cannot get them down. Besides this, he has nearly always a pressing sensation around the chest, coughs very much, and is not able to sleep well.

Examinations of the stomach and the œsophagus.—1. October 25, 1888, at 8 A.M. Patient drank coffee one hour before. As soon as a part of the stomach-tube was pushed into the œsophagus a coffee-brown liquid was ejected, in which there were some remnants of food and many epithelial cells present. Thereupon the patient drank 100 c.c. water. At the processus ensiformis I did not hear any swallowing sound during the time that the patient drank. On introducing a part of the tube into the œsophagus, water of a neutral reaction came out. Thereupon the tube was pushed farther into the stomach, without any resistance, and the patient ejected from his stomach through the tube about 70 c.c. of a coffee-brown liquid. Reaction acid, hydrochloric acid present (phloroglucin-vanillin test), the degree of acidity being 40 (*i.e.*, 40 c.c. of $\frac{1}{10}$ normal sodium-hydrate solution neutralized 100 c.c. of the examined fluid).

2. November 5th, at 9 A.M.—On account of loss of

---

[2] Ziemssen: Handbuch, vii., i., p. 49.

[3] Berlin. klin. Wochenschr., No. viii., 1888.

appetite the patient had not eaten anything since 2 P.M. of the previous day. The tube was introduced for a length of 46 ctm. from the teeth; a pulpy mass (150 c. c.) came out, in which were present small particles of bread; reaction acid, lactic acid, no hydrochloric acid; acidity, =4. The patient drank 100 c. c. water, the tube was introduced 45 ctm., the water came out somewhat turbid by the admixture of mucus and food-remnants; microscopically there were many epithelial cells and micrococci. After the water had come out, the tube was pushed, without being taken out, farther and with but a slight resistance it passed into the stomach; the patient was told to empty his stomach, but only a few drops of a clear fluid was obtained. This proved that the stomach was empty.

3. November 8th. The patient partook of breakfast and then drank water; he was examined an hour later. The tube was introduced for a distance of 36 ctm., when there appeared a fluid containing no hydrochloric acid; thereupon the tube was pushed, without any further resistance, into the stomach, and by expression a fine chyme was obtained containing hydrochloric acid and peptone.

4. November 13th. The patient took eggs, coffee, and a little softened white bread, then he administered his method of bringing the food down into the stomach by means of pressing (bringing the muscles of expiration into play, after having made a deep inspiration, with closed glottis). An hour later, shortly before the examination, the patient was told to press several times again. The tube was introduced to a distance of 48 ctm., and during expiration only 8 c. c. of a turbid fluid were obtained; there were present very minute pieces of bread and many epithelial cells, but no hydrochloric acid; thereupon the tube was pushed, without any resistance, into the stomach; now there came out a chymous fluid with hydrochloric acid. The patient drank 200 c. c. water; the tube was introduced about 40 ctm., and the water came out with a gush.

5. November 16th. Patient took breakfast at home and administered his method of forcing down his food. The œsophagus was examined an hour later, and found empty. The pharynx-vault was tickled with the finger to induce vomiting, but without success. Thereupon the tube was introduced into the stomach, and a fine chymous fluid, containing hydrochloric acid, was obtained. The stomach was then filled with air by means of a tube and bulb; the air did not emerge, striking the outside wall of the tube. By keeping the tube open the stomach was emptied of the air; afterward the lower part of the œsophagus was blown up. A considerable quantity of air could be blown into it without returning, but upon increasing it still more the air began to escape upward through the upper part of the œsophagus, striking the outside of the tube-wall. During the inflation of the œsophagus there was observed, at both sides of the vertebræ below the inferior margin of the scapulæ, a somewhat more tympanitic resonance, but that was not very decided.

It is evident, from the history of this patient, that the difficulty in bringing the food into the stomach slowly developed a few days after the fall and finally led to a complete dysphagia. The examinations showed that the contents of the stomach were normal. The examinations with the stomach-tube (a thick Nélaton was used for this purpose) show, firstly, that the passage through the œsophagus to the stomach is perfectly free, for the thick tube passed into the stomach without any resistance; secondly, that the œsophagus, in its lower third, must be saccularly dilated, as the distance from the teeth to the cardia (measured with the tube) is 48 ctm., whereas, in the case of this patient, even taking into consideration his large frame, it ought normally to be not more than 40-41 ctm. In this cavity the tube, leaning on the wall of the œsophagus, was compelled to assume with its lower end the form of a semicircle, and thus produced this high figure. That the patient is really unable, in swallowing, to bring even liquids down to his stomach, except by the pressing action, is proven by the fact that swallowed water could always be taken out from the œsophagus by means of the tube, whereas immediately afterward the tube, pushed into the stomach, brought up part of the stomach-contents, containing hydrochloric acid.

The best way to perform this experiment is with two differently colored fluids, and I take the liberty of demonstrating to you, gentlemen, the experiment, which I have so often done at my residence.

The patient, about an hour before, took a cup of coffee and some softened crackers; thereafter he administered his pressing actions. Now I insert the tube into the œsophagus of the patient as far as the cardia, in order to see whether the œsophagus is empty. As you see, a coffee-brown liquid (about 40 c.c.) comes out, in which there are small particles of bread. Congo-paper retains its red color in this liquid. The œsophagus consequently was not empty. Now, after having emptied the œsophagus by means of the tube, I will ask the patient to drink a glass of water (250 c.c.). Should the water, by simply swallowing it, not arrive at the stomach, I shall be able to obtain the same from the œsophagus by means of the tube. I therefore introduce the tube again, and you see how the water comes back unchanged; a few flocculi are floating in it, some bread, and epithelia; but otherwise the water returned unchanged and in the same quantity; congo-paper does not change its color in same. Now I push the tube farther through the cardia into the stomach, and have the patient press a little. You see now a coffee-brown liquid coming out, with very small pieces of bread; the congo-paper turns dark blue. This is the coffee which the patient drank at home, and brought into his stomach by his spontaneous pressing action.

The water—which the patient drank just a little while before and which was obtained without any discoloration from coffee—clearly proves that it has not been in contact with the coffee contained in the stomach; it remained above the stomach, in the œsophagus. This proves, therefore, that by swallowing this patient does not accomplish the passage of anything into the stomach, but that all accumulates in the œsophagus and remains above the cardia.

As the œsophagus can hold quite a considerable quantity of liquid in its inferior part, it must be dilated. In order to ascertain approximately to what distance the dilatation of the œsophagus extends, I tried to determine at what length of the introduced tube the water of the quite filled œsophagus began to come out, when the patient made an expiratory effort; the lowest figure I obtained was 36 ctm. When there was only a small amount of fluid above the cardia, the tube had to be introduced 46-48 ctm. in order to allow the fluid to come out. Thus the utmost dilatation must be situated at the lowest part of the œsophagus. Further, I tried, to fill the inferior part of the œsophagus with air, and examined the back of the patient in order to find out whether the resonance had undergone any change; but the variations were so slight and so doubtful that I would not take them into consideration.

Following Meltzer, I investigated the fact whether in my patient was preserved the faculty of vomiting. By tickling the posterior wall of the pharynx with the finger I could not bring on vomiting. When the stomach had been filled with air, the latter did not return by striking the outside wall of the tube. Both these circumstances would prove, according to Meltzer, that the path from the stomach to the œsophagus is occluded.

I conclude therefore, from a consideration of the above-ascertained facts, that we have to deal with a case of dilatation of the œsophagus unaccompanied by any anatomical stenosis. Formerly this case would have been considered as a primary dilatation of the œsophagus. But, as it is very difficult to assume a primary dilatation of the œsophagus, Silvius Stern[1] attributed, as a cause of the so-called primary dilatations, either a previous œsophagitis or a paralysis of the œsophagus. Likewise, Meltzer[1] was in doubt as to the existence of a primary dilatation of the œsophagus, and deduced that in his case the spastic contraction of the cardia was the cause of the dilatation. I, like Meltzer, would not consider my case as a primary dilatation of the œsophagus, but am inclined to look for the cause of dilatation in another previous disturbance.

---

[1] Silvius Stern: Archiv der Heilkunde, Bd. xii., p. 434.

There are three possible explanations of this difficulty in bringing down the food from the œsophagus into the stomach without any anatomical stenosis being present :

1. Paralysis of the œsophagus ; the swallowed particles would remain above the cardia, which is normally easily closed, as the œsophagus is lacking in its contractile power.

2. Spastic contracture of the cardia, which, Meltzer suggests in his case, the contractions of the œsophagus cannot open.

3. A lack in the reflex relaxation or opening of the cardia during the act of swallowing. It was shown by Meltzer[2] that every act of swallowing easily opens the cardia by reflex action. Supposing that the centre or the circuit of this reflex action is in any way disturbed, so that the cardia does not relax when swallowing, there will necessarily result a slight difficulty in transferring the food from the œsophagus into the stomach.

Should you ask which of these three disturbances exists in my case, I would have to confess that it is very difficult to decide with certainty, but that the third disturbance is here most probable.

In my patient the dysphagia, as can be seen in the history, was developed slowly after a fall. During the first two weeks the patient experienced no difficulty whatever when eating, but later on he observed that he had to drink warm water in order to effect the passage of the food. After a while the warm water had no effect, and the patient instinctively began to exercise the pressing motions which helped him.

Now, had the œsophagus (by some trauma or contusion) become paralyzed after the fall, or had the cardia spastically contracted—a dysphagia would, naturally, have appeared immediately after the fall; for the paralyzed œsophagus could not bring the food into the stomach; nor could the spastically contracted cardia give free passage to the food into the stomach.

But it would be quite different with the third class of disturbance, viz., lack of the reflex relaxation of the cardia when swallowing. This disturbance, being the slightest, would hardly appear at first ; the contractions of the œsophagus would succeed in opening the cardia and enable the passage of the food forward. Notwithstanding, the œsophagus would have more work to do than necessary for the normal relaxation of the cardia when swallowing. With the lapse of time the œsophagus would tire, and some food-remnants would remain above the cardia. But these remnants, meanwhile, would dilate the inferior part of the œsophagus ; the dilated œsophagus naturally would contract with difficulty. In this way there would gradually—after a certain degree of dilatation had taken place—appear that difficult dysphagial condition where, upon swallowing, nothing enters the stomach by the natural way.

Only once did I feel a slight resistance at the cardia on introducing the tube into the stomach ; usually I found no resistance whatever. This would speak against the spastic contracture and favorably for our conjecture. [illegible] I could not make the patient vomit, nor did the air —blown into the stomach through the tube—return, striking the outside wall of the tube. According to Meltzer both these facts would speak in favor of a spastic contracture of the cardia. The question arises, Are these two signs indeed conclusive? The failure of the faculty of vomiting in the beginning of the illness would tend to prove that the cardia is contracted and that the stomach, therefore, is not able to open the occlusion. But in an advanced state of the disease, where there already exists a large dilatation of the œsophagus and the latter either does not contract at all or contracts without effect—we could very well imagine that, as soon as the stomach, at the beginning of the act of vomiting, throws up a part of its contents through the cardia into the œsophagus, these contents are not ejected because the œsophagus does not contract itself ; and, besides, the ejected matters, if they did not immediately return through the opened cardia into the stomach, would find room enough to stay in the dilated œsophagus. Thus may be explained the absence of the faculty of vomiting, though the cardia be not spastically contracted.

With regard to the second point, viz., that the air did not strike the tube—we sometimes find, even in healthly people, when the stomach is filled with air to a certain degree of tension that the air passes rather through the pylorus than through the cardia, so that the air does not strike the tube.

Though we must more or less resort to hypothesis as to the original disturbance of the patient, notwithstanding this the anatomical and clinical conditions are apparent. There is a dilatation of the inferior part of the œsophagus without any material stenosis (for any anatomical stenosis could not be overlooked with the thick tube), and all swallowed matters remain at first in the inferior part of the œsophagus above the cardia. By spontaneously diminishing the size of the thorax after a deep inspiration with closed glottis (pressing), the patient is able to drive the gathered food-substances—by means of the pressure he exerts on the filled œsophagus—into the stomach.

To Meltzer[1] belongs the credit of having described particularly in his article these conditions of bringing down the food spontaneously.

In order to prove that the food remains above the cardia, Strümpell[2] and Meltzer examined the vomited (from the œsophagus) matters, and always found a neutral[3] reaction, whereas the contents of the tube pushed into the stomach had an acid reaction.

This condition is better shown by the coffee and water experiment, as I have fully described it above.

In reference to the therapeutics in such cases, it would always be best to feed the patients for a long time only by means of the tube. It would be possible, perhaps, to partly diminish the dilatation of the œsophagus. My patient would not be fed in this way, and I had to content myself with the following treatment :

1. The patient is allowed to take only fluid or semifluid things.

2. After every meal the patient must perform his pressing action for a long time.

3. Every evening, before going to bed, the œsophagus is emptied and washed by means of the tube (the patient is now able to do it all alone).

4. The patient introduces the tube into his stomach once every day, in order to relax the cardia.

In the ten days during which the patient has lived according to these rules, he has gained one pound in weight, slept well, never coughed, and has been able to eat more and much easier. He now looks much better, is more encouraged, and contented.

122 East Fifty-ninth Street.

Chloride of Gold and Sodium receives every now and then a new therapeutic impetus. Just now it is recommended by Dr. George W. Rachel for whooping-cough. It is given in doses of ♏ ij. of the two per cent. solution, every two hours.

[3] The food-matters above the cardia not having been in the stomach can have also an acid reaction by organic acids, as can be seen from the above-described tests, but they *never* do contain hydrochloric acid.

SOME DERMATOLOGICAL DON'TS.

By GEORGE THOMAS JACKSON, M.D.,

CHIEF OF THE DERMATOLOGICAL CLINIC, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK CITY.

Don't make your diagnosis from the history of a case, because if you do you will often be led astray. Make it from the eruption that you see, and then substantiate or destroy this by the history of the case, if you will.

Don't fail to think of the possibility of every case being either syphilis or eczema; and

Don't fail to master these two diseases as thoroughly as possible; because, if you learn to recognize these two, you will have gone a long way in diagnosis. If they can be excluded, then the field of possible "might be's" is considerably narrowed.

Don't make the diagnosis of syphilis on account of a syphilitic history, because you can often get a history of syphilis in a non-syphilitic case.

Don't expect much, if any, history of syphilis in a woman, because you very frequently will not get it. This is not because they are "gay deceivers," but because in them the early symptoms of the disease are often so slight that they are not observed by them.

Don't throw out the diagnosis of syphilis on account of an eruption itching, because some syphilides, especially the papular variety, do itch at times. The *not* itching of an eruption is better presumptive evidence of syphilis than is itching positive evidence against it.

Don't make the diagnosis of lichen planus from the presence of flat angular papules with depressed centres alone, because identical lesions will at times be met with in eczema, syphilis, and psoriasis.

Don't depend upon getting the bleeding points springing out of the delicate pellicle after carefully scraping off the scales for your diagnosis of psoriasis, because you can produce the same thing in other diseases. In fact,

Don't depend upon any one symptom, but make your diagnosis from the general make-up of the disease as a whole.

Don't forget that many diseases of the skin are dependent upon disturbances in the general health of the patient. Therefore,

Don't fail to inquire into the performance of the functions of the various organs of the patient, and to put him into as good a physical condition as possible.

Don't tell your patient that it is dangerous to cure his skin disease rapidly, because it is not. If you

Don't know how to treat the case, ask advice of someone who does.

Don't encourage the popular notion that there is danger of an eruption striking in, because it never does.

Don't give arsenic for every skin disease, and, especially,

Don't give it in acute eruptions. Its sphere is in the chronic scaly eruptions, such as chronic psoriasis.

Don't forget that most cases of pruritus are due to internal causes, and that in them external treatment is wasted; and

Don't forget the bed-bug and the pediculus as possible causes of the trouble.

Don't forget that the greatest secret in the treatment of eczema, and many other skin diseases, is not what particular drug or formula is "good for" the disease, but a knowledge of the great principle that acute diseases need soothing remedies, and subacute and chronic diseases need stimulation.

Don't expect to cure an inveterate eczema with thickened skin by means of a soothing ointment, such as that of the oxide of zinc, because you will only waste your time, and the patient's money.

Don't use tar in an acute eczema, because it is a stimulant, and what we want at this time is to soothe the inflamed skin. It is appropriate to a subacute or chronic case.

Don't allow water to touch any form of eczema, because it always irritates in such a case.

Don't use a thick ointment on the hairy scalp, because it makes a disagreeable mess of the hair, and will not be "popular" with your patient. Even lard is not a pleasant vehicle for such applications. Vaseline and the oils are more elegant excipients.

Don't order the hair to be cut from the head of a young or old woman in any disease of the scalp, because, except in the case of a peculiarly stupid or careless patient, it is never necessary, and always disagreeable to the woman.

Don't allow a patient with ringworm to go to school, because if you do you will be responsible for the spread of the disease.

Don't pronounce a ringworm case well and incapable of spreading the contagion until you are sure that it is well; and

Don't be sure about it until there are no more "stumps" on the scalp, and you can find no more of the fungus in the hair.

Don't use the name "barber's itch" for anything but trichophytosis barbæ, because it is well not to use terms loosely to cover several different diseases.

Don't use chrysarobin on the face or scalp, because it is very apt to cause a good deal of dermatitis with œdema, and to stain the skin a deep mahogany-red.

Don't forget to caution a patient to whom you have given chrysarobin, not to touch his face with his hands after applying the drug, because if you do you will have either a mad or a frightened patient in your office.

Don't pronounce a patient addicted to the excessive use of alcoholic beverages on account of his having rosacea, because there are lots of other things besides alcohol that will cause it.

Don't use the positive pole of the battery for the needle in destroying hair by electrolysis, because if you do you will leave more or less permanent marks in the skin.

Don't apply a sulphur preparation after using a mercurial upon the face, or *vice versa*, because if you do you will raise a fine crop of comedones.

Don't use a camel's hair brush for making applications of corrosive sublimate, because if you do some of the salt will be left on the brush each time it is used, and you will soon have a stronger solution than you bargained for. Always use a little cotton on a wooden toothpick, or a splinter of wood.

Don't allow a fine-toothed comb to be used on the scalp, because it scratches and irritates the scalp.

Don't encourage or advise the use of pomades on the healthy scalp, because they are prone to become rancid, and inflame the scalp. They are also unnecessary if the hygiene of the scalp is properly looked after.

Don't forget that dandruff is the most frequent cause of premature baldness, because, if you remember this, you may be able to prevent the fall of someone's hair for some time. Therefore,

Don't fail to treat every case of dandruff.

14 East Thirty-first Street.

The Therapeutic Action of Borneol.—Experiments as to the comparative therapeutical value of Borneo camphor, Ngai camphor, and borneol prepared artificially from oil of turpentine, have been made and published by Dr. Stockman. It appears that the action of borneol, whether in the form of Ngai camphor, Borneo camphor, or artificial borneol, is similar to that of laurel-camphor, but that the borneol has the advantage of being less poisonous, so far as the heart is concerned. Borneol, laurel-camphor, and menthol are closely related to the alcohol group in their physiological action, menthol approaching it most nearly. Bornoel is less irritating locally than laurel-camphor, and can be given in much larger doses than the latter without causing untoward cerebral symptoms. Both borneol and menthol differ from ordinary alcohol in powerfully dilating the peripheral vessels.—*Journal of Physiology.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 29, 1888.

PROTECTION FOR AMERICAN PHYSICIANS.

THERE is a growing feeling, among physicians in this city at least, that if the principle of protection be applied to some classes of workers it might with equal justice be applied to the doctor.

The law against importing contract labor, for example, is intended to protect the so-called laboring classes. But it is hard to see why this class alone should be protected.

There are, we are told, numbers of physicians, so called, coming over from Germany by every steamer, who are not legally qualified to practise even in their own country, and so they turn their adventurous steps to a new land where medical laws are less severe.

In Germany no one can practise medicine without passing the state examination. Even a university diploma of M.D. is of no value as giving legal status to the physician. The men who are found incapable of practising the profession of medicine in Germany come over here, therefore, settle down among the German districts, put out a sign, and pay visits for twenty-five or fifty cents.

Some of the older German physicians of this city have of late had their practice seriously curtailed by these adventurous interlopers. The injustice of the thing is still more flagrant from the fact that American physicians, however well qualified, cannot go over to Germany and engage in practice there.

We do not assert that these unqualified and disqualified immigrants all come from Germany. A certain number probably come from France, Italy, and England. But, at any rate, the evil is a decided one and deserves some attention from the profession. It would be possible to check it in a measure if a law separating the licensing from the diploma-giving power were enacted. Until that is done we see no special remedy. But the condition here referred to furnishes an additional argument to the many already existing for the enactment of a law creating in this State an independent board of medical examiners.

HYSTERIA IN ITS SURGICAL RELATIONS.

IN a recent critical review covering the subject indicated above (*Revue de Médecine*) Dr. Georges Guinon discusses the subject of traumatism and hysteria. Much of what he says is only the presentation in a systematic way of what has long been known; and the assumption that French science has been chiefly concerned in formulating our knowledge of hysteria and traumatism is characteristic of the intellectual isolation not infrequently to be noted in our esteemed Latinic colleagues.

The fact that hysteria may develop from nervous shocks and traumatism, and may show itself in manifold ways, cannot be too strongly insisted upon; and it is true that most valuable contributions have been made to the semeiology of the hysterical condition by Charcot and his pupils.

The importance to the surgeon of recognizing hysterical from organic affections is well illustrated by Guinon in the following hypothetical case: Two men fall and break the collar-bone in the same way. They are treated by a surgeon, who applies a bandage in the most approved and skilful manner. Fifteen or twenty days later both return with paralysis of the arm. In the one case, however, the paralysis is due to an exuberant bony callus at the seat of fracture, compressing the brachial nerves, in the other the paralysis is hysterical.

The various forms of nervous disturbance following sudden injuries, with or without great emotional excitements, are familiar through the works of Erichsen, Page, and others, and are described by Guinon, who shows that among them are true examples of hysteria and neurasthenia.

Among special traumatisms which may give rise to hysterical symptoms are those of the cranium. Here Ballet has shown that there may be veritable partial convulsive attacks which simulate those of Jacksonian epilepsy, and which may lead to the belief in a focal lesion of the brain, but which are in reality only hysterical.

Monoplegias of various types, but especially of the arms, hysterical coxalgia, hysterical affections of the knee and other large joints, hysterical affections of the small joints simulating rheumatism, pseudo mal de Pott hystérique, hysterical contractures from the application of surgical apparatus, and hysterical disorders resulting directly from traumatism of surgical operations, are all discussed by our author. Of all these types, however, the hysterical knee is the most frequent. Among seventy cases observed by Charcot, thirty-eight were of the knee, eight of the wrist, four of the shoulder, and two of the ankle.

Especial importance attaches itself to the collection of signs and symptoms which inform us of the presence of the hysterical state. These are both of a positive and negative character. The positive signs lie almost entirely in the domain of disturbances of general and special sensation. Anæsthesia in various degrees and forms is a thing which is, perhaps, most frequently seen. When cutaneous it may take the form of patches or bracelets, or it may be diffused over the whole arm and hand, forming anæsthesia *en manche de veste*, or if of the lower extremity, anæsthesia *en gigot*. If it is a joint which is affected, there may be anæsthesia of adjacent parts with local cutaneous hyperæsthesia in the neighborhood of the affected joint. This sensitiveness of the skin, together with lack of pain on deep pressure, is known as "Brodie's sign," and is often of great importance.

The pharynx sometimes shows anæsthesia. Hemianæsthesia, though not pathognomonic of hysteria, is an especially characteristic symptom, particularly if it is not stable but can be transferred by suggestion, the action of magnets, etc. Cutaneous anæsthesia of hysterical origin involves all the cutaneous sensations, and often even the muscles.

The eyes may also show hysterical signs in the shape of concentric contraction of the visual field, dyschromatopsia, with reversal of the visual field of colors, monocular polyopia, micropsy, and macropsy. Taste, odor, and smell may be abolished on one side or both.

If the patient has contractures or rigidity of the limb, the use of chloroform or gas will soon disclose whether the symptom is organic or functional.

If paralysis exist, atrophy may occur even in hysteria, but the wasting is slower and less marked; electrical examination never shows any degenerative reaction; and hence this test is of extreme value in paralytic cases. It must, however, be most carefully made.

It is always difficult to tell to what extent the pains so often felt are hysterical. The reaction of the patient to drugs and to suggestions may, however, throw much light upon this point.

It is never to be forgotten that true hysteria may exist in connection with real organic disease. This fact complicates many cases and renders the diagnosis of traumatic, neurasthenic, and hysterical states a task that calls for all the ingenuity and acuteness of the surgeon.

In this country, too, it is comparatively rare to see the peculiar stigmata of hysteria so well marked as they are in France. In particular, traumatisms such as railway accidents, falls, nervous shocks, etc., are much more liable to cause neurasthenic than hysterical states.

ARTHRECTOMY, OR EROSION OF JOINTS.

At a late meeting of the Royal Medical and Chirurgical Society (*The British Medical Journal*, November 17, 1888), Mr. Edmund Owen read a paper having this title. Though the operation of scraping a diseased tissue was not a new procedure, yet its adoption in the treatment of pulpy or of chronic suppurative disease of a joint was of comparatively recent adoption. The first account of it, and the success which attended it, was by Mr. Wright, Surgeon to the Children's Hospital, Manchester. It appeared in *The Lancet* of 1881. This he supplemented by a review of sixteen cases of arthrectomy in the *Medical Chronicle* of July, 1885. The construction of the hip-joint rendered it unsuited for treatment by arthrectomy in chronic disease, but as a supplementary measure to resection of the head of the femur it was likely to prove of great value. The epiphyses might often escape mutilation while the whole of the pulpy synovial membrane and all other diseased tissue were cleared out of the articulation. The cartilage joining the epiphysis with the shaft was neither disturbed nor trenched upon, and thus the risk of the patient recovering with a greatly shortened limb was obviated. Indeed, it was even possible that the patient might recover not only with a limb of normal length, but with a joint in which the movements were but little if at all interfered with. Such a result, however, was neither to be expected nor aimed at. After the operation the limb was to be kept absolutely stiff and fixed in splints for many months, and if at the end of that time a certain range of movement were discovered, the joint might be left to shake itself free, no manipulations being resorted to. In all probability the knee would be synostosed and straight. In the case of pulpy or chronic suppurative disease of the knee-joint the operation was admirably adapted, provided that the disease was not too far advanced, so that the bones were extensively implicated, and that the patient was the subject neither of general tuberculosis nor of albuminoid degeneration. In short, arthrectomy was the proper operation in most of those cases in which resection had hitherto been performed. Over resection it held this great advantage, that it took away from the articular surfaces only such tissues as were actually diseased. On several occasions it had been noticed that after the joint had been thus thoroughly cleared of elements which were of a diseased or suspicious nature the health of the patient had shown an immediate and marked improvement, appetite and general health altering for the better, and permanent convalescence being at once established. Speculations were made upon the possible influence of the bacilli tuberculosis. The improvement which followed upon the clearing out of all the diseased tissues was as notable as that which often followed the amputation of a sarcomatous limb or a scirrhous mamma.

It is to be regretted that Mr. Owen should have selected so unfortunate a name as arthrectomy for the operation of scraping joint surfaces. Arthrectomy, if it has a meaning, denotes excision, the very operation which Mr. Owen would have us avoid. The principle on which erosion is based is not a new one. The idea of removing only what is diseased and useless, and saving all that is healthy, applies to all conservative surgery in its broadest sense. Indeed, so far as the joints are concerned, Volkmann and his pupils have for years been prominent advocates of precisely the same thing that Mr. Owen now brings to the notice of his British *confrères* as something rather new.

HYSTERORRHAPHY, THE NEW OPERATION FOR DISPLACEMENTS OF THE UTERUS.

The cervix uteri having been subjected to an incalculable amount of more or less harmless stitching, both by the experts and those willing to become so, it is now proposed to devote a stitch or two to the hitherto strangely neglected fundus uteri. We may as well confess *à priori* our feeling in favor of hysterorrhaphy, as Dr. Howard A. Kelly, of Philadelphia, has called this new operation, with which his name has become justly and prominently associated.

The fame of this gynecologist has too long grown, *pari passu*, with the number of his cervical stitches. It is time that the trachelorrhaphist should be told that the cervix is not the universe, even in a strictly uterine sense. He should learn that there may be complete cervical happiness, although the fundus still weeps way down in the hollow of the sacrum, on account of a prior attachment. The hysterorrhaphist is, of all persons, the one best qualified to restore the just equipoise of things uterine by placing his beneficent stitches where they really belong, and, no longer truckling to that arrogant gynecic monopolist, the cervix uteri, in spite of all its amiable accessibility. Of course, sewing the fundus is an innovation of a somewhat revolutionary kind. If there needs must follow division in the serried ranks of the conquering hystero-stitchologists, let the new party lines be drawn on this local issue of cervix or fundus. For, that both parties will continue to stitch to the end of all time, nobody can reasonably doubt.

Seriously speaking, however, the new operation of attaching the uterus to the abdominal parietes is a rational procedure in otherwise unmanageable cases of displacement. The operation itself is neither very difficult nor specially dangerous. It extends a just hope of relief to those whose sufferings are not likely to be overestimated.

From a recent discussion of the subject, which followed the reading of a paper by Dr. C. C. Lee (MEDICAL RECORD, November 10, 1888), it appears that primary hysterorrhaphy has now been done about one hundred times, with but a single death attributable to the surgical interference. For a new operation, that always presupposes laparotomy, this is certainly an encouraging exhibit, especially when it is remembered that only in a few instances failure to relieve was noticed.

The technique of the operation is fully set forth in a paper by Dr. Kelly (*The American Journal of Obstetrics*, January, 1877), and the article of Dr. Lee already referred to, as well as the recent discussion of it before the New York Academy of Medicine. In Germany the operation goes by the name of ventro fixatio uteri, which would give it a more restricted meaning than the term hysterorrhaphy implies.

The precise indications for suturing the uterus in order to correct a malposition have not yet been found. A conservative surgeon will certainly not rashly undertake the operation before all other means to secure respite from suffering have been tried. With the claims now made in behalf of electricity, of uterine massage by the method of Brandt, with Alexander's operation for those cases in which the uterus is still freely movable, hysterorrhaphy can have but a limited field of applicability. A distinction should be made between primary and secondary hysterorrhaply. The former is the operation we have been speaking of. It is a laparotomy performed for no other reason than that of securing fixation of the uterus by suture. Secondary hysterorrhaphy means that, in the course of an abdominal section undertaken for some other purpose, it is found expedient to also attach the uterus to the abdominal wall for the correction of any malposition that happens to exist. It is apparent, therefore, that the primary operation will be called for far less frequently than the secondary.

EUTHANASIA as applied to criminals and dogs is speedily becoming a high science in this city. It being settled that an alternating 3,000-volt current passed from brow to nucha is a pleasurable and facile mode of descent to Avernus, the problem of making felicitous the last hours of dogs is taken up. The way has been to put impounded dogs in a crate and submerge them. The Board of Health has had constructed an immense air-tight box into which illuminating gas can be poured. Ninety dogs placed in this box and submitted to the gas died within four minutes. Seventy-eight ounces of chloroform killed twenty dogs in two minutes, but with more struggling than when the gas was used.

News of the Week.

DR. CASPER WISTER, of Philadelphia, died on December 20th, aged seventy-one years.

DR. JOSEPH LOVING, a prominent young physician, died at the Central Insane Asylum of Columbus, O., on December 20th, of brain trouble.

DR. C. N. CAMPBELL, one of the oldest physicians of Dutchess County, N. Y., died on December 20th. He was a graduate of the New York Medical University, and was widely known. He was surgeon in the One Hundred and Fiftieth New York Volunteers, and served through the war. He was President of the Poughkeepsie Civil Service Board, a member of the Board of Pension Examiners, and a leading member of the Dutchess County Medical Society.

NEW YORK POST-GRADUATE HOSPITAL.—The New York Post-graduate Medical School and Hospital gave an informal reception to its friends on December 21st, at the hospital building, 226 East Twentieth Street. The guests of the institution were conducted through the various well-filled wards.

During the past year 382 new patients, including 100 infants, have been treated in the wards, and 5,756 new patients have in that time been treated in the dispensary. It is the present aim of the Faculty to purchase the building the institute now occupies, and its members have already agreed to furnish $20,000 of the $60,000 required to accomplish this purpose. The Board of Directors is anxious to secure funds for the foundation of a lying-in ward. The medical school supports itself, but the hospital is constantly, as are all charitable institutions, in need of funds. This is especially true with regard to its current expenses. During the last year 282 operations were performed on the house-patients of the general hospital; 100 babies were treated—60 were cured, 24 died. Over 29,000 visits were made to the dispensary, which was an increase of 5,823 over the previous year.

POLITICS AND INSANE ASYLUMS.—A despatch from Yankton, Dak., says that the Trustees of the Insane Asylum in that place have removed the Superintendent, Dr. R. Buchanan, by a vote of the majority of the board, and appointed Dr. James Roane, of Yankton. Buchanan was appointed by the present board as soon as it was granted full powers by the courts. Combinations in the board are responsible for his removal, and not anything he has done to merit discharge.

CREMATION IN PHILADELPHIA is not thriving. The new crematory near Philadelphia has recently been obliged to reduce the price of incineration from $50 to $20. Since May twenty bodies have been cremated—barely enough to pay expenses. The Philadelphia crematory is the biggest in the world, but the stockholders lament "the multitude of cheerful fires, the glorious host of light," that indicates rational disposal of the body and prompt payment of dividends.

DR. IRA RUSSELL, of Winchendon, Mass., died on December 19th, after a week's illness, of pneumonia, aged seventy-four. He was a native of Rindge, N. H., and a graduate of Dartmouth College and of the New York University, Medical Department. He entered the army as surgeon of the Eleventh Massachusetts Regiment, and subsequently served in many positions on the general medical staff and in the field. At the close of the war he was honorably discharged with the rank of brevet Lieutenant-Colonel. In 1875 he established a home for nervous invalids at Winchendon. He was the author of a number of practical articles relating to his specialty. He was Vice-President of the New York Medico-Legal Society, a past Vice-President of the Massachusetts Medical Society, and a member of the Masonic order and of the Loyal Legion.

JAMAICA-GINGER INEBRIATES.—One hears occasional stories of Jamaica-ginger inebriates, and recently it is stated that a Boston grocer was arraigned for selling Jamaica ginger as an intoxicant without a license. Jamaica ginger contains, we are told, sixty-nine per cent. of alcohol and three per cent. of ginger. It would soon cause too much gastric disturbance to be long and continuously used as an intoxicant.

THE CHRONIC INSANE OF NEW YORK COUNTY who have heretofore been confined on Ward's and Blackwell's Islands are to be removed, in part at least, to the pavilions recently built on the County Farm at Central Islip, L. I. The Commissioners have spent $200,000; they have bought 1,000 acres of land, and put up pavilion accommodations for 300 patients—a sufficiently modest result. They now want a quarter of a million more to continue the beneficent work.

WE ADMIRE the optimistic patriotism of an esteemed Western contemporary, the *Journal of the National Association of Railway Surgeons*, which concludes an editorial upon American Medical Colleges as follows: "We are purely American in every sense of the term, and have no sympathy with the chronic cranks for the European methods of education. America is far in advance now, and will continue to be.

"'My country, 'tis of thee,
Sweet land of liberty,
Of thee I sing.'"

WHAT IS TO BECOME OF THEM? was the question first asked of medical graduates. Now the question is applied to the immense number of specialists cropping up in every department. Regarding this subject, Sir Morell Mackenzie said some wise things in his address before the British Laryngological Society, November 14th: "Throat specialism," he said, "appears to be even in danger of becoming fashionable; at any rate the number of its votaries has lately been increasing and multiplying with a rapidity which makes one inclined to wonder, with Abernethy, 'What is to become of them all?'" Sir Morell gives some good advice to those intending to become specialists (*Provincial Medical Journal*). He recommends all throat specialists to practise general medicine or surgery for the first ten years of their professional career, while devoting themselves at the same time to their specialty. "In my opinion," he says, "only those who have acted as general practitioners for some years, or who have held appointments as physicians or surgeons to general hospitals, are thoroughly equipped for practising as specialists."

The next piece of advice is equally worthy of consideration. He continues: "Give your attention mainly to pathology and therapeutics, seeking to enlighten darkness and eradicate error in these important matters rather than to the invention of apparatus. One may earn some cheap renown, no doubt, by modifying the mechanism of a snare, or applying the electric light in some slightly novel fashion to laryngoscopy, but an ambition that is satisfied with such triumphs can hardly be called 'an infirmity of noble minds.'" The last advice is perhaps the best, it is the great gospel of work. "Work steadfastly," he concluded, "whether the subject be recondite or apparently trival; observe and test everything, and bring your results here to be criticised by your fellow-workers."

THE SMALL-POX HOSPITAL AT SYRACUSE has been the subject of considerable discussion during the past week. The Health Officer of the city charged that there was the grossest incompetency in its management, the nurses being ignorant, untrustworthy, and insubordinate.

DEMONSTRATION IN FAVOR OF A POPULAR PROFESSOR.—During the past week the students of the University Medical College have been much exercised over the resignation of Professor Faneuil D. Weisse, the well-known author and the popular professor of practical and surgical anatomy in that institution. The causes can be briefly stated. The chair of surgery became vacant by the resignation of Professor Wright, and Professor Stimson, succeeding to the same, left the chair of anatomy empty. Professor Weisse offered to fill the chair of anatomy for the remainder of the term free of charge, but the new professor of surgery consented to occupy both chairs of surgery and anatomy, and obtained the permission of the faculty to appoint a substitute of his own selection. The resignation of Professor Weisse very properly followed, as after a service of a quarter of a century in teaching the higher branches of anatomy, the ignoring of his voluntary service was a blow at his self-respect. The students became indignant at the course pursued by the faculty, and not only requested the withdrawal of the resignation but the unconditional appointment of Professor Weisse to the full chair of anatomy. Of course the faculty will do as it pleases. Students must not rule. But if the vote were taken outside the faculty and by the profession at large, there would be no doubts concerning the qualification of Professor Weisse for the place.

THE HOG AHEAD.—It is stated that the United States Government has paid more money in the investigation of the disease of hogs than it has for all the diseases affecting the human race.

FEMALE PHYSICIANS IN TURKESTAN.—There are a number of female physicians in Turkestan, but they have little to do on account of the prejudice of the Mohammedan population. The only way in which they can secure any patients at all is by reversing the accepted order of things and paying them a fee. The same disinclination to accept the services of female physicians exists among the women in certain parts of Siberia. At Omsk every woman who consents to enter the lying-in hospital receives a present of two or three rubles.

CREMATION IN SWEDEN.—The Swedish Cremation Society, which was founded in Stockholm in 1882, now numbers 3,000 members and subscribers. A provisional crematorium has been established in one of the cemeteries. The system employed is that of Mr. Klingsenstierna, the president of the society, and is said to be very cheap.

Society Reports.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting held Tuesday, December 4, 1888.

The President, Dr. Geo W. Jacoby, in the Chair.

Dr. M. P. Jacobi presented a case of supposed

TUMOR OF THE PONS.

The case was that of a child, ten years of age, the illness dating from a fright three years before. The immediate symptoms had been trembling, lasting two weeks. A little later the child had commenced to walk as if intoxicated, and to have difficulty in using the hands. About three months after the seizure headache had been complained of for a number of weeks. The child had also commenced to grow fat, and the head had increased in size. During the past summer the circumference of the head had increased one-third of an inch. At the present time the child was very fat, the chest and abdomen being particularly large. There was no actual paralysis. All of the muscles would respond to faradism, the peroneal muscles only requiring a current particularly strong. There was, however, a progressive paresis. The child could not sit upright, and the head fell to the right side. She could walk only if supported, and all of the finer movements of the hands had been lost. There was intermittent external strabismus in the right eye, and choked disk in both eyes, referred to a descending degeneration. The appetite was abnormally increased. There had been no pain throughout, excepting the headache referred to, and no sensory disturbances.

The case of tumor of the pons reported by Dr. Hun, of Albany, had presented strikingly similar symptoms. In this case the pons had been uniformly enlarged by a slowly infiltrating gliomatous growth.

Dr. Sachs felt especially indebted to the author of the paper for the opportunity of renewing an old acquaintance with this interesting case, which he had seen and lectured upon at the Polyclinic, in April. At that time the size of the head had been about as at present. The general condition was as now, but the patient had been able to walk better. She had been able to walk across the floor with the assistance of her father, moral, rather than physical, support being required. The gait, however, had been uncertain, and the patient had reeled, he had thought, to the right side. He had also found the paresis greater upon the right than upon the left, and had noted an apparent paralysis of the right abducens. The changes which he remarked were a progressive paresis of the arms and legs, and slight increase in the size of the head. In the spring the speaker's diagnosis had been tumor of the cerebellum favored by the paralysis of the abducens, which had a long course along the ventral aspect of the cerebellum and might be affected by pressure from the growth. Such a fact would also explain the intermittent character of the symptoms noted by Dr. Jacobi. He had not appreciated the objections to this diagnosis, toward which the reeling and the vomiting certainly pointed. The knee-jerk was more marked upon the right. The ankle clonus had been obtained upon the left, and not upon the right at all. Dr. Hun's had been a very rare case. The majority of cases of tumor of the pons had presented different symptoms. He made these remarks simply to justify his diagnosis. Dr. Jacobi had gone more fully into the case and possibly had developed further evidence.

Dr. W. A. Hammond asked why a multiple lesion was excluded.

Dr. Sachs suggested that if one lesion could not be definitely located, the indications for a multiple lesion must be even more obscure.

Dr. Hammond inquired as to the condition of the intelligence.

Dr. Jacobi thought that the intelligence was normal. The child could relate the circumstances of the initial fright very clearly, and had made inquiries in regard to the prognosis in her case.

Dr. Hammond noted a tendency to staccato speech. He had seen a number of cases of tumor of the cerebellum. He referred especially to the case reported by Dr. Gibney. The distinctive symptom of tumor of the cerebellum, when uncomplicated with pressure upon the pons, was inco-ordination without paralysis, while that of pons lesions was a gradually increasing paresis. He had seen also a good many cases of injury to the cerebellum by arrow wounds, bullet wounds, etc., perhaps twenty cases in all. These were more likely to furnish indications in regard to the functions of the cerebellum than cases of tumor where the effects of pressure complicated those of the destructive lesion. He had never seen a case of either tumor or injury of the cerebellum without vertigo and nystagmus.

Dr. Jacobi closed the discussion. The diagnosis had been studied between an intra-cranial tumor and a diffuse hypertrophic sclerosis of the brain with a generalized lipomatosis. The latter was excluded by the absence of the more distinctive symptoms of pseudo-muscular hypertrophy, and by the existence of the choked disk, the latter pointing positively to intra-cranial disease. Diffuse sclerosis was, among other symptoms, invariably attended by convulsions, which had been entirely absent in this case. Intra-cranial tumor was diagnosed therefore, by exclusion as well as by the positive symptoms and by further analysis, located in the pons.

The speaker had not known that the case had been previously seen by Dr. Sachs, or that a clinical lecture had been delivered upon it. The later stage of the affection accounted for the main differences between the symptoms reported by her and those noted by Dr. Sachs. She had not, however, referred to a paralysis of the external rectus, but to an intermittent spasm. The muscle could at all times be readily exercised. The history of vomiting, too, was limited to two occasions in May, and was not more marked than might have been accounted for by some digestive disturbance. Further, there was not only inco-ordination in this case, but complete incapacity. In lesions confined to the cerebellum standing was simply difficult. In this case standing was impossible.

Dr. W. A. Hammond followed with a paper entitled

WEAK HEART AND ITS TREATMENT.

The paper referred simply to weakness of the muscular structure of the heart, uncomplicated by dilatation or valvular disease. The affection was very common, and while it might be fatal in its results, it might also be entirely relieved by treatment, which could be resolved into medicinal, gymnastic, and dietetic.

Digitalis was the main medicinal remedy. The author had never observed the so-called cumulative effect of this drug. He thought, on the contrary, that it required increasing doses. He administered the infusion in two drachm doses for two weeks, when he increased the dose one-fourth, repeating the increase at the end of the second fortnight. Convallaria he considered uncertain and unreliable. Strophanthus he thought of more value. Where there was intolerance to digitalis this drug might be given. Strychnine was a valuable remedy in weak heart. He prescribed one grain in one ounce of dilute phosphoric acid, ten drops three times a day. Cocaine was a valuable remedy, one-fifth grain being given three times a day. It had been his custom to add two grains to one pint of Malaga wine, a wineglassful being used at a time.

Inhalations and hypodermic injections were required often in the weak heart of disease. Hypodermically he had used brandy, digitalin in a one to twenty grain dose, and nitrite of amyl, two drops diluted with thirty drops of glycerine.

Glonoin was useful in a one to one hundred grain dose.

Medication was, however, only temporarily useful. Exercise was required for the permanent relief of this condition. Mounting stairs was mentioned as a convenient form of exercise. People living in the country might mount hills. The physician should, however, be in attendance, and the exercise should be suspended when the action of the heart had accelerated fifteen beats per minute, to be resumed upon its tranquillization. The author's sanatorium in Washington would contain a modified treadmill in which such exercises could be taken.

The dietetic treatment of weak heart referred particularly to ingested liquids, the quantity of which should be limited. By lessening the amount of liquids ingested the total amount of blood in the body was diminished and the work of the heart lightened. In some cases he had reduced the daily quantity to twelve ounces, with marked improvement within forty-eight hours. The diet was further modified so as to reduce the amount of fat where this was excessive. The author made no claim of originality in this treatment. He was aware of the work of Oertel and others. He presented the matter, however, as approved by his own experience and observation.

Dr. Leale referred to the numbers of recently enlisted soldiers who fell in the grand review in Washington, their previous occupations having been largely sedentary and predisposing to weak heart, which failed them in response to the demands of the unusual exertion of this occasion. In five hours ten ambulances had been filled, the speaker having been detailed to pick up those who thus fell by the way. The weak heart of typhoid fever and diphtheria were briefly alluded to. This was a condition often seen in children from close school attendance or other sedentary habits having failed to develop heart-muscle sufficient to accommodate the growing frame.

Dr. Heinemann had been very much interested in Dr. Hammond's paper. He was interested to know of the sanatorium referred to. He had, during the past year, visited a number of these institutions in Europe, and thought it to be regretted that in this country we had so generally failed to avail ourselves of the peculiar advantages which they afforded.

Weak heart was one of the most common conditions met with in medicine—it was almost as common as dyspepsia. While actual disease of the heart might not be detected in connection with the condition, the sounds would be found not what they should be, and the radial artery would be found never more than half filled with blood. The causes for weak heart were often dyspepsia, lithiasis, and excesses of various kinds—alcoholism, tobacco, and excessive coitus. The treatment should be directed first toward the removal of the cause—bad hygienic surroundings, anæmia, or whatever it might be. Iron or the oxygen treatment were often efficacious.

In regard to digitalis, he could say that he had seen the cumulative effect, although not perhaps the cumulative effect of the materia medica, which he thought was exaggerated. He had seen the pulse, under the influence of digitalis, one day eighty or ninety, and the next day forty or fifty, as strong or stronger than before. Convallaria was, he thought, useful combined with digitalis in the cases of heart failure in children and in cardiac dilatation. Cocaine was valuable in curing anæmia, as well as for its direct action upon the heart. In a recent case he had prescribed the wine of cocaine, intending to combine it with iron; but at the end of a week had found the anæmia so much improved that the iron was considered unnecessary.

In the diagnosis of the weak heart of adolescence alluded to by Dr. Leale, it was well to bear in mind the condition of congenital narrowing of the aorta, to which attention had been directed by Fraenzel. This was not infrequently a cause of sudden death in young people. The speaker would not pretend to diagnose the condition, except by exclusion.

In regard to the question of exercise, he hoped that treatment would not be systematized upon the plans in vogue in Europe. In the Black Forest there were paths specially designated for pulmonary diseases, and other paths for other complaints. He had seen a sign on one of these paths reading, "This is the end of the Oertel treatment." There was a rule, too, that a sanatorium for pulmonary affections should be built at the foot of a hill, so that the patient, having taken his exercise in climbing the hill, can easily get back. There was also conflicting evidence as to the value of these "cures." The Oertel treatment was antagonized by the brothers Schott, who substituted a system of resisted movements, a species of wrestling with the nurse under the supervision of the physician. Cardiac calisthenics was the appropriate title of these exercises.

Dr. Hammond closed the discussion. He was pleased to have called out so many interesting remarks. One interesting point in etiology had, however, he thought, failed of recognition. This was that a normal heart, under ordinary circumstances, might become a weak heart by simple increase in the general body-weight. He had a personal experience upon this point. His ordinary weight was two hundred and forty pounds. When it increased to two hundred and sixty pounds, which it did about twice a year, he was troubled with weak heart. He was then accustomed to apply his own prescriptions as to diet and exercise. In this way he could reduce his weight thirty pounds in thirty days. He then again ate and drank what he pleased. When he went up to Mackinaw this summer he had been suffering from weak heart. When he returned he could climb anywhere, and was perfectly comfortable.

It might not be out of place to add that the eminent surgeon recently deceased in this city had lost his life from this cause. The case had been at first reported as one of cerebral hemorrhage, but hemorrhage, except into the medulla, does not instantly destroy life, and subsequently the conclusion of heart failure had been reached.

The meeting adjourned.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending December 15, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	21	8
Scarlet fever	210	31
Cerebro-spinal meningitis	1	1
Measles	334	20
Diphtheria	133	23
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

An Epidemic of Jaundice at Glasgow.—Dr. Russell reports a number of cases of icterus occurring in June and July last, in five families living in the poorer quarters of Glasgow. A man, aged thirty-six, died on July 8th, with jaundice supposed to be due to yellow atrophy of the liver. The day before his death his son was taken down with the same symptoms, and died in a short time. Another child died a week later, and still another the day following the last. In another family, six children suffered at the same time from jaundice. The author attributed the outbreak to the defective sewerage and insanitary condition of the neighborhood.

A Chapter in Etiology.—A correspondent sends the following quotation from a letter received by him in relation to a case: "I am sure the etiology of the sequelæ was anti, and not propter, the operation."

INDEX.

A

Abdomen, gunshot wounds of, 25.
Abdominal neurosis and exploratory laparotomy, in the male, 63; pressure in hysteria, 643; section, conclusions from a second series of one thousand consecutive cases of, 553; mortality of, 705; lessened mortality of, and the causes thereof, 602.
Abscess, cerebral, following extensive necrosis of the temporal bone, 329; cold, dangers of iodoform injections in, 161; hepatic, bursting through the lung, 300; pelvic, 323, 325; pulmonary, treatment of, 301, 536, 736.
Acetanilide or antifebrin, influence of, on proteid metabolism, 360.
Acetic acid as a disinfectant in midwifery, 618.
Acetonuria and its relation to diabetic coma, 740.
Acetophenidine, 9.
Acid, boracic, fatal dose of, 308; therapeutic uses of, 41; toxicological effects of, 531; camphoric, in skin diseases, 384; carbonic, rectal injections of, in the treatment of vomiting of pregnancy, 175; free hydrochloric, the new test for, 41; salicylic, as an antipyretic, 86; uric, relation of excretion of, to disease, 70.
Acne, ointment for, 692; treatment of, 565.
Acoustics, applied to the human chest, in physical diagnosis, 713; physiological, a study in, 589.
Acrania, 181.
Addison's disease, 224.
Adhatoda vasica, 268.
Adjustable frames for taking facial measurements, 522.
Adrenals, disease of, without bronzing, 481.
Age and childbearing, 664.
Agnew, Dr. C. R., and the New York Pathological Society, 742; resolutions on the death of, 46.
Air, disinfectant of, 166; respired, organic poisons in, 68.
Alaninate of mercury, 480.
Albinos, why they do not see well, 720.
Albumin and casts and renal inadequacy, value of, in the diagnosis and prognosis of diseases of the kidney, 341.
Albuminous urine, toxicity of, 536.
Albuminuria, pathogenic conditions of, 157; relation of, to life insurance, 342.
Alcohol, as a cause of disease, 274; as a therapeutic agent, 300; as an antipyretic, 88; in phthisis, 451; toxicity of, 619.
Alcoholic excess, deaths from, in London, 160.
Alcoholic treatment of disease, opposition to, 210.
Alcoholism, and crime, 82, 630; therapy of, 712.
Alimentary canal, microbes of the, 69.
Alimentation, defective, diseases of the skin due to, 172.
Allen, Dr. Dudley P., the radical cure of hernia, 141.
Allen, Dr. H. P., middle-ear disease and politzerization, 220.
Allen, Dr. Thomas G., improved form of club-foot shoe, 438.
Alopecia, contagiousness of, 608.
Amaurosis from a carious tooth, 384.
Amblyopia from tobacco, 110.
Ambulance corps, system of drill for, 387.
Amenorrhœa, santonin in, 207.
American Academy of Medicine, 511, 627.
American Association of Genito-urinary Surgeons, 325, 348, 375.
American Association of Obstetricians and Gynecologists, 322, 346, 371.
American Climatological Association, 336, 357, 382.
American Dermatological Society, 330, 354, 378.
American Gynecological Society, 324, 347, 374
American Laryngological Association, 335, 356, 381.
American medical schools, status of, in Europe, 541
American medical student, 13
American Neurological Association, 327, 350, 377.
American Ophthalmological Society, 135, 352.
American Orthopedic Association, 334, 355, 379.
American Otological Society, 100, 328.
American Physiological Society, 337, 359
American Rhinological Association, 403.
American surgeon abroad, 708.
American Surgical Association. 316. 344, 370.
Ampère, definition of, 61.
Amputation, of an arm, muscular retraction occurring during the, 66; of leg, stump undressed for eight days, recovery, 155.
Amylene, hydrate of, 307.
Anæmia in children, mineral waters in, 150.
Anæmias, real and false, 732.
Anæmic sore throat, 196.
Anæsthesia, chloroform or ether, 652; combined cocaine and chloroform, 612; new use for ether during, 636; profound, muscular retraction occurring under, 66.
Anæsthetic, mint as an, 15; the best, 496.
Anæsthetics, local, 552.
Analgesiac, antipyrin as an, 475.
Anchor-splint for fracture of the jaw, 420.
Anchylosis, extensive, of the skeleton, with diaphragmatic breathing, 601; of the knee, operation for, resulting in gangrene, 478; of the knee, subcutaneous operation for, 370.
Anderson, Dr. Winslow, unsuccessful vaccination and immunity against smallpox, 155.
Aneurism, aortic, 76, 77, 79; aortic, surgical treatment of, 552; thoracic, 108.
Aneurisms. and tubercle bacillus, 647; treatment of. by iodides and antipyrin, 564.
Angina Ludovici, 572.
Angina pectoris, 163, 165.
Angina pseudo-gastralgic, 163, 165.
Angioma, cavernous, sesquichloride of iron in, 196; of the epiglottis causing hæmoptysis, 83.
Anglo-German controversy, the, 482.
Aniridia, 147.
Ankle-joint, excision of, 320.
Anode and cathode, 110.
Anodyne, phenacetin as an, 15.
Anthrarobin, as a substitute for chrysarobin and pyrogallic acid, 41; in dermatological practice, 332.
Antifebrin, as an antipyretic, 86; in epilepsy, 28; in sciatica, 646.
Antipyretic, a new, pyrodin, 542.
Antipyretic action of ox-bile, 88.
Antipyretic, strophanthus as an, 570.
Antipyretics, 80, 164; etiology and pathology of increased bodily heat in relation to. 85.
Antipyrin, action of, 164; and belladonna, 623; and spirit of nitrous ether, malpractice suit for prescribing, 654; as an analgesiac, 477; as an antipyretic, 86; for the relief of labor pains, 557; in cephalalgia, 180; in labor, 210; in seasickness, 567, 633; poor showing for, 551; rashes from the use of, 649.
Antisepsis, simplified, 394; intestinal, in typhoid fever, 73.
Antiseptics, incompatibility of, 481; reaction against, 595.
Antiseptic solution, a safe, 596.
Antiseptic surgery and seal rings, 689.
Antiseptic troches for the prevention of diphtheria, 568
Anus, imperforate, 643, 659.
Aorta, aneurisms of, 76, 77, 79; aneurism, surgical treatment of, 552; rupture of the arch of the, 571.
Aphasia, and apraxia, 497, 515; following typhoid fever, 196; occurring during the secondary stage of syphilis, 179; temporary, from a cerebral tumor, 89; traumatic, relieved by trephining, 425.
Apostoli, Dr. G., electrical treatment of uterine fibroids, with answers to objections and citation of novelties, 253.
Apostoli's method of treating uterine fibroids, 10, 63; unfavorable view of, 46.
Apraxia and aphasia, 497, 515.
Army and Navy news, 26, 56, 83, 112, 139, 166, 195, 221, 252, 306, 383, 411, 438, 468, 494, 523, 549, 579, 607, 634, 661, 689, 720, 743.
Arnold, Dr. John W. S., death of, 513.
Arsenic and eucalyptol, medical antisepsis by subcutaneous injections of, 251; in rheumatoid arthritis, 621.
Arsenical paralysis with symptoms of locomotor ataxia, 124.
Arterial changes in phthisis, 390.
Arteries, auscultation of, 69; congenital narrowing of, 128.
Arterio-sclerosis, generalized, in angina pectoris, 163.
Artery, central retinal embolism of, 137; pulmonary, with two valves, 406; wound of internal mammary, 536.
Arthrectomy, 687; or erosion of joints, 756.
Arthritic diseases, use of mineral waters in, 358.
Artificial foods, composition of, 167.
Ascites, chylous, 126, 189.
Ascites, pathogenesis of, 190; simulating ovarian tumor, 687; treatment of, by faradization, 702.
Aseptic, boiled water as an, 662.
Ashmead, Dr. Albert H., hæmoglobinuria and rheumatism, 155.
Aspergillus in the external auditory canal, 446.
Aspermia, cause of, 161.
Association of Acting Surgeons of the U. S. Ar[illegible] 624, 740.
Association of American Anatomists, 339.
Association of American Physicians, 314, 341, 368.
Asthma, relation of the nasal and neurotic factors in the etiology of, 382; spasmodic, relation of, to chronic hypertrophic rhinitis, 91.
Astigmatism, is it a factor in the causation of glaucoma? 352; meridional, 353; relation between corneal and total, 431.

Atheroma in the minute vessels of the pia mater, 200.
Athetosis in an infant, 95.
Atmosphere, conditions which tend to render the, aseptic, 382.
Atomizer for warming and spraying vaseline, 111.
Atomizer-tip forced down a patient's throat, 64.
Atrophia uteri, acquired, 422.
Auditory canal, external, aspergillus in, 446; diseases of, 441; keratosis obturans, 445.
Auditory exostoses, convenient method of operating for, 603.
Aural snare, an improved, 102.
Aural vertigo relieved by excision of the membrana tympani and malleus, 100.
Auscultation, arterial, 69.

B

Babcock, Dr. John Lord, lepra nervorum, 285.
Bacillus of cancer, 83.
Bacteria, influence of, in the digestion of children, 564; of sea-phosphorescence, 745; of virulent, weakening of, 648.
Bacteriology, importance of, in ophthalmology, 434.
Balbivalier prize in medico-chirurgical science, 46.
Baldwin, Dr. Benjamin J., a perplexingly uncertain fee, 691.
Ball, Dr. A. Brayton, some difficulties in the diagnosis of typhoid fever, 225.
Ballad of a busy doctor, 140.
Baloch, Dr. Kálmán, death of, 159.
Balsam of Peru as a surgical dressing, 423.
Barium and digitalis, 440.
Barnes, Dr. E. J., the catheterization of women, 277.
Baruch, Dr. Simon, are operations for lacerated cervix uteri justifiable? 740.
Bath, cold, as an antipyretic, 88.
Baths, hot-water, in chronic synovitis of the knee, 537; Russian, physiological effects of, 537.
Battershall, Dr. Jesse P., notice of book by, 517.
Betol, 248.
Bichromate of potassium, poisoning by, 580.
Bigelow, Dr. Blake, imperforate hymen, 704.
Bile in urine, Oliver's test for, 140.
Biliary obstruction, fever accompanying, 461.
Billroth and Mackenzie, 72.
Binghamton Asylum, 98.
Biting the finger-nails, an accident from, 125.
Bladder and kidney affections, differential diagnosis of, 349.
Bladder, removal of tumor of, through the male urethra, 395; ruptures of the, 535; sarcoma of the, 620; spontaneous expulsion of a tumor of, after perineal section, 481; extroversion of the, 68.
Blepharospasm, 353.
Bleyer, Dr. J. Mount, the phonograph in physical diagnosis, with experiments, and its future, 586.
Blindness, hysterical, in the male, 137.
Blistering, dangers of, in heart disease, 747.
Blood, circulation of, in the cornea, 69.
Blood-corpuscles, diminution of the number of, in enteric fever, 563; red, origin and regeneration of, 337.
Blood, human, diagnosis of, 127; human and animal, 592; methods of diluting, 301.
Blood pressure and transudation, 268; effects of the douche upon, 82.
Blood stains, human, recognition of, by the microscope, 663.
Blood-vessels of the pia mater, inflammatory and other changes in the, 197.
Bogdanovski, Dr., death of, 744.
Bohemia, hospital notes in, 109.
Boils, and felons, ointment of the nitrate of mercury in, 564; the treatment of, 43.
Bone disease, exploring needle in, 106.
Booth, Dr. J. A., progressive muscular atrophy with anæsthesia, 236.
Borax and boracic acid, advantage of, 537.
Boric acid, and lanolin in the skin diseases of children, 542; fatal dose of, 308; therapeutic uses of, 41; toxicological effects of, 531.
Borneol, therapeutic action of, 754.
Bozeman, Dr. Nathan, renal tenesmus, a result of chronic cystitis and ureteritis, successful treatment by kolpo-uretero-cystotomy and intravaginal drainage combined with elevation and support of the uterus and ovaries, 116.
Brain and spinal cord, injuries of the, 544.
Brain, disease of the motor area of the, 301; injuries, recovery from, 603; multiple softening of, 108; non-decussation of anterior pyramids of, 340.
Brain surgery, three cases of, 322.
Breast, cancer of, in a man, 488.
Brewer, Dr. George E., successful lumbar colotomy, with sphincter formation, in a case of congenital absence of rectum and anus, 643.
Bright's disease, and climate, 383; a study of the arteries and veins in, 1; increase in deaths from, in Massachusetts, 46; pilocarpine in, 68; acute, coccus of, 486; acute, lesions of, 108; chronic, cardiac changes in, 342; retinal changes in, 731.
British Medical Association, 273, 298; address on obstetrics at the meeting of the, 191; section of diseases of children, 406; section of public medicine, 407; section of therapeutics, 410.
Bronchiectasis, surgical treatment of, 736.
Bronchitis, capillary, of children, oxygen in, 618; chronic treatment of, 495; in the aged, treatment of, 13; treatment of, 140.
Broncho-pneumonia and pulmonary abscess complicating ulcerative colitis, 571.
Brooke, Dr. J., activity of the scarlet-fever poison after a year, 125.
Brown, Mr. Baker, the story of, 608.
Brown, Dr. Charles G., an anchor splint for fracture of the jaw, 420.
Brown, Dr. Moreau Roberts, postnasal punch forceps, 719.
Brown, Dr. Sanger, experiments on special sense localizations in the cortex cerebri of the monkey, 113.
Bruce, Dr. J. D., papoid and veratrum viride in diphtheria, 448.
Bruck, L., notice of book by, 132.
Brunt, Dr. Henry Dickson, malarial retinal hemorrhage, 36.
Buck, Dr. Albert A., notice of book by, 516.
Buck, Dr. Albert H., reflex influences in the production of naso-pharyngeal catarrh, 176.
Budge, Dr. Ludwig Julius, death of, 188.
Bulbar lesions, pharyngeal and laryngeal paralysis due to, 382.
Bull, Dr. Charles Stedman, a contribution to the surgical treatment of membranous opacities in the vitreous, 238.
Bunts, Dr. F. E., electricity in gynecology, 61.
Burch, Dr. T. Hamilton, acute pemphigus—death, 125.
Burke, Dr. Martin, diphtheria, 605.
Burns, potassium permanganate in, 196, 552.
Burritt, Dr. H. L., death of, 72.
Busey, Dr. Samuel C., the Congress of American Physicians and Surgeons, 278.
Byford, Dr. W. H., notice of book by, 516.

C

Cadaverin, 654.
Cæsarian section, the new, 347.
Caffeine in heart-failure, 74, 308.
Calculi, uric-acid, of the kidney, treatment of, 456.
Calculus, nasal, 145; renal, boro-tartrate of potassium for, 590; urethral, 376.
Calomel, as a diuretic, 510; hypodermic injection of, in syphilis, 104; large doses of, in pneumonia, 260.
Cammann, Dr. D. M., a new pocket stethoscope, 578.
Campbell, Dr. C. N., death of, 757.
Campbell, Dr. F. R., notice of book by, 517.
Camphor-poisoning, fatal case of, 578.
Canada Medical Association, 543.
Canadol, 166.
Cancer, and vegetarianism, 167; microbe of, 83, 224; of the breast in a man, 488; of the larynx, 509; of the larynx, results of the treatment of, 16; of the uterus, carburetted hydrogen in, 195; renal, without urinary symptoms, 503.
Cancerous tongue, removal of, 456.
Canned food, poisonous, 99.
Carbohydrates, digestion of, 735.
Carbolate of mercury, 26.
Carbo-oxygen in consumption and other forms of wasting disease, 560.
Carbuncle, scraping out or erosion of, 29, 48; treatment of, 307; hot water in the treatment of, 420.
Carburetted hydrogen in uterine cancer, 195.
Carcinoma, and syphilis, 28, 293, 424; intratracheal, with cancer of the thyroid, 168; of the peritoneum, 75; primary intranasal, 146; prognosis of, after surgical interference, 674.
Cardiac dyspnœa, 565.
Cardiac muscle-cells, deglutination of the, 484.
Carlsbad salts, artificial, 73.
Carotid hemorrhage, successful treatment of, 563.
Carpenter, Dr. A. B., treatment of uterine fibroids by Apostoli's method, 10.
Carr, Dr Walter Lester, the catheterization of women, 278.
Castle, Dr. F. A., ingrowing toe-nail, 740; purified wool-fat, 25.
Catalepsy in both mother and child, 600.
Cataract, cineraria maritima in, 124, 267; complicating aniridia, 147; extraction, excessive hemorrhage after, 545; treatment of, 432.
Cataract knife, a new form of, 136.
Catarrh, acute, etiology and pathology of, 404; naso-pharyngeal, reflex influences in the production of, 100, 176.
Catha edulis, 421.
Catheter fever, 303.
Catheterization of women, 195, 277.
Cattle, pulmonary tuberculosis in, 218.
Cell life, influence of the nervous system on, 362.
Cellulitis, pelvic, removing of swelling after, 675.
Centenarians, 223; rarity of, 248.
Cephalalgia, antipyrine in, 180.
Cerebral disease, value of eye symptoms in the localization of, 687.
Cerebral hemorrhage, progressing, management of, 666, 683.
Cerebral localization, discussion on, 341.
Cerebral, special sense localizations in the monkey, 113.
Cerebral surgery, 160, 275; drainage in, 657.
Cerebral tumor, a case of, 89.
Cerebro-spinal meningitis, epidemic of, 358.
Cerium oxalate in the treatment of dysmenorrhœa, 12.
Cerumen, accumulation of, in the external auditory canal, 443.
Cervical spine, tumor of the, 378.
Cervix uteri, amputation of, for carcinoma, 374; dilatation *versus* divulsion of, 588; Emmet's and Schroeder's methods of operating on, 545; extensive laceration of, 655; fissure of, 565; harmlessness of lacerations of, 44; lacerations of, are operations for, justifiable? 740; Dr. Atlee on, 712.
Chambers, Dr. M. L., oxalate of cerium in dysmenorrhœa, 12.
Chapman, Dr. Henry C., notice of book by, 518.
Charcot, Dr. G. M., notice of book by, 517.
Chemical analysis of healthy and diseased urine, book notice, 517.
Cheese-poisoning, 270.
Cheesman, Dr. T. M, death of, 72.
Chicago post-garduate school, 704.
Chicken cholera microbes and the rabbit pest, 654.
Child, hysterical spasm of the œsophagus in a, 66; poisoning by kerosene of a, 64; suppurating ovarian cyst in a, 76.
Childbearing, age and, 664.

Children, cerebral paralysis in, 649 ; diseases of, therapeutical value of mineral waters in, 149 ; of Ishmael, 130 ; oxygen in the capillary bronchitis of, 618 ; simulation of disease by, 43 ; summer drink for, 99.
China grass as a wound dressing, 423.
Chinese college of medicine, 710.
Chloride of zinc for intra-uterine use, 592.
Chloroborate of sodium, 439.
Chloroform, antiseptic value of, 468 ; or ether anæsthesia, 652 ; the pupil as a guide in the administration of, 181.
Chloroform water as a solvent for drugs, 494.
Chlorosis, suppressing menstruation for, 524.
Cholecystenterostomy and gastro-enterostomy, 513.
Cholecystotomy with ligation of the cystic duct, 292.
Cholera, and its fostering conditions in the endemic area, 408 ; inoculations, 744; quinine in, 224; Sir J. Fayrer on, 662.
Cholera infantum, and diarrhœa, 165 ; and the weather, 59, 153, 279 ; prevention of, 184.
Cholesterine crystals in the retina, 211.
Chordee, treatment of, 369.
Chorea, after parturition, 509 ; hereditary, 271, 378 ; mineral waters in, 150 ; of the soft palate, 403.
Choroid, considered as an elastic organ, 433 ; tensor muscle of the, 432.
Christmas-eve disaster, 748,
Chromic acid in excessive sweating, 610.
Chronic insane of New York County, removal of, 758.
Church, Dr. Charles A., two placentas—one child, 180.
Churchill, Dr. J. H., organic union of the medical schools and universities, 718.
Chylous ascites, 126, 189.
Cigarette, the poison in the, 430 ; smoking, one more effect of, 745.
Cinchona, false, 746.
Cincinnati polyclinic, 697.
Cineraria maritima in cataract, 124, 267.
Circumcised by a maternal impression, 535, 718.
Circumcision, reform of, 223.
Cirrhosis, experimental, 292 ; of the liver in a rabbit, 573.
Clavicle, supra-acromial dislocation of the, 657.
Clavus, treatment of, 28.
Climate, and Bright's disease, 383 ; for consumptives, 663.
Climates, aseptic, without altitude, 726.
Club-foot, Morton's method for the immediate reduction of, 334 ; improved form of shoe for, 438 ; treatment of, by immediate restoration of the parts to their normal position after tenotomy, 621 ; treatment of, by the Thomas wrench, 334.
Cocaine, conjunctivitis, 353, 421, 662 ; influence of the discovery of, on ophthalmic surgery, 736 ; poisoning, acute and chronic, 480 ; unusual effect from the use of, 291 ; urethral injections of, for the relief of neuralgic pains, 182 ; used in operating for single harelip, 479.
Coe, Dr. Arthur H., case of supernumerary nipple associated with maternal impression, 479.
Cold, artificial, for yellow-fever hospitals, 608.
Cold bathing in fever, 164.
Cold, sloughing of the cornea from, 248.
Colds and bronchitis, treatment of, 140.
Cole, Dr. Palmer C., tests for diabetes mellitus, 475.
Colic; renal, differentiation from renal tenesmus, 121 ; treatment of, 293.
Colitis, croupous, 107.
Coloboma, symmetrical, of the two upper eyelids, 434.
Colo-colostomy, a successful case of, 612.
Colon, absorption of water by the, 466 ; rupture of, following ovariotomy, 655 ; ulcers of, 107.
Colorado, climate of, 358 ; climate of, in the treatment of pulmonary disease, 337.
Colorado Springs, invalids suited for treatment at, 337.
Colotomy, inguinal, for malignant disease of the rectum, 706 ; lumbar, 68 ; lumbar, with sphincter formation, in a case of congenital absence of rectum and anus, 643, 659.
Color-blindness, detection of, 137.
Coma, diabetic, relation of acetonuria to, 740.
Compressed air below the sea level, 242.
Conchilla Valley, climate of, 242.
Congenital absence of both eyes, 420.
Congenital absence of rectum and anus, successful lumbar colotomy, with sphincter formation in, 643, 659.
Congenital ovarian tumor, 648.
Congress and quarantine, 131.
Congress for the study of tuberculosis, 217, 249.
Congress of American Physicians and Surgeons, 131, 278, 295, 309, 341, 362, 384.

Conjuror's jack, 216.
Consanguinity in marriage, 464, 467.
Constipation in infancy, 620 ; in woman, treatment of, 307.
Constriction, bodily, in the causation of disease, 318.
Consumption, carbo-oxygen in, 560 ; hot dry air inhalations in, 693.
Consumptives, climate for, 663 ; Florida as a resort for, 54.
Contagious diseases, weekly statement, 27, 83, 112, 140, 167, 195, 221, 306, 412, 439, 494, 523, 549, 580, 608, 634, 661, 689, 720, 744, 756.
Copper phosphate in tuberculosis, 480.
Corcoran, Dr. G. M., jaundice, 305.
Corlett, Dr. William T., diseases of the skin due to defective alimentation, 172.
Cornea, fluorescine in the diagnosis of lesions of the, 733 ; sloughing of, from cold, 248 ; transplantation of, 72, 99, 710 ; treatment of ulcers of, 353 ; viewing the circulation of the blood in the, 69.
Corns, treatment of, 28.
Corpses as parlor ornaments, 190.
Corpulence, guiding principles of treatment of, 67.
Coronary artery, stenosis of, 163.
Corset, scientific attack on the, 594.
Corson, Dr. Hiram, sixty years of practice by, 45.
Cortex, diagrams of different areas of the, 340.
Cortex and spinal cord, part taken by the cells of, in producing muscular contractions following stimulation of the cortex cerebri, 360.
Cortical localization of cutaneous sensations, 328.
Coryza powder, 643.
Cough, significance of, 685 ; uterine, treatment of, 691.
County Society, the, and the water-supply, 397, 510, 605.
Courtesy, professional, 71.
Court plaster, death in the, 223.
Courts, medical cases in the, 391.
Coxitis, senile, mechanical treatment of, 356.
Cramps in the legs, 412.
Creasote, parenchymatous injections of, in pulmonary phthisis, 508.
Cremation in Philadelphia, 757 ; in Sweden, 758.
Creolin as an antiseptic, 224.
Crime of a medical journalist, 397.
Criminality and alcoholism, 82.
Crothers, Dr. T. D., should inebriates be punished for crime?, 473.
Curable percentage in general practice, 186.
Current, continuous, in the treatment of fibroid and other diseases of the uterus, 546.
Curtis, Dr. B. Farquhar, enterostomy for acute intestinal obstruction, 233.
Cyst, in the heart, 509 ; ovarian, and cirrhotic ovary, 77 ; suppurating ovarian, in a child, 76.
Cystitis, acute, treatment of, 636 ; and ureteritis in woman, 116 ; saccharin in, 177, 440.
Cystotomy, suprapubic, 344, 393, 508.

D

Dabney, Dr. S. G., on the hydrobromate of homatropia as a mydriatic for determining errors of refraction, 290.
Darlington, Dr. Thomas, malaria in a dog, 646 ; observations on the etiology of pneumonia, 672.
Dayton, Dr. William A., convictions regarding the nostrils in, 698.
Deaf-mutism : its pathology, causes, and treatment, 533.
Deafness, from stimulation of the retina, 308 ; pilocarpine in, 224.
Deane, Dr. Cunningham W., death of, 513.
Death, by electricity, 623, 678 ; from fright, 65 ; hyperpyrexia, the cause of, 70 ; sudden, from distention of the stomach, 40.
Deemer, Dr. J. T., ergot in obstetric practice, 750.
Deer-horns as medicine, 738.
Deformities, artificial, Virchow on, 680.
Deglutination of the cardiac muscle-cells, 484.
De Jager, Dr. S., tuberculosis treated by tannin, 290.
Delirium tremens, methylal in, 272, 509.
Delivery of the after-coming head, 293.
Denison, Dr. Charles, the extension-windlass method of treating fractures of the long bones, 169.
Denslow, Dr. Le Grand N., urethral irritation in the male as a source of disease, 413.
Dental abscess, recurrent, 196.
Deodorizer of fecal matter, common slag as a, 72.
Dermatitis herpetiformis, 354.
Dermatitis plantaris and palmaris, 379.
Dematological don'ts, 754.
Dermatology, progress in, 103.
Dermoid cyst of the mediastinum, 26.
Dermoid tumor of the abdominal wall, 373.
Dessau, Dr. Henry S., the value of condensed milk as a substitute for mother's milk, 207.
D'Estrees, Dr. Debout, oxaluria, especially in its relation to uric acid, 665.
Dextrocardia, 268, 479.
Diabetes mellitus, and malaria, 747 ; Hofmeister on, 14 ; relations of, with alterations of the pancreas, 25 ; tests for, 475 ; neurotic symptoms in association with, 301.
Diagnosis, mistaken, 606 ; physical, phonograph in, 586.
Diaphoretics, antipyretic action of, 88.
Diarrhœa, chronic, treatment of, 163 ; of nurslings, lactic acid in, 604 ; persistent, in locomotor ataxia, 40 ; powdered talc in, 131 ; summer, treatment of, 140.
Diathesis and temperament in disease, 614.
Dietz, Dr. William D., a system of drill for ambulance corps, 387.
Digestion of children, influence of bacteria on, 564.
Diphtheria, 605 ; antiseptic troches for the prevention of, 568 ; from a fowl, 307 ; laryngeal, best internal remedy for, 592 ; local treatment of, 293 ; local treatment of, by Vlemincks' solution, 703 ; origin of, from animals, 579 ; origin of, from birds, 23 ; papoid and veratrum viride in, 448 ; peroxide of hydrogen in, 446 ; some clinical features of, 446 ; spread by cats, 633 ; sudden heart-failure in, 574.
Diphtheritic paralysis, 456 ; strychnine in, 28.
Disease, classification of, 274 ; in books, 631.
Diseases, common to man and the lower animals, 409 ; of the heart and circulation in infancy and adolescence, book notice, 516 ; of women, book notice, 516.
Disinfectant, burning sulphur as a, 135 ; in midwifery, acetic acid as a, 618 ; of air, 166.
Disinfection of instruments, 452 ; of surgical instruments and dressings, 535.
Dislocation of the cervical vertebræ, 377.
Dispensaries, useless, 677.
Dissolution and evolution, and the science of medicine (book notice , 132.
Diuretic, calomel as a, 510 ; hot-water clyster as a, 96.
Diuretics, antipyretic action of, 88.

Diverticulum, gigantic intestinal, 548.
Dlauhy, Dr. Johann, death of, 216.
Doctor, the, at home, 570; the title of, 596.
Domville, Dr. Edward J., notice of book by, 517.
Doses, small and pleasant, 80.
Douche as affecting blood-pressure, 82.
Douglass, Dr. Henry B., pepsin in surgery, 730.
Drainage, bad, and phthisis, 17.
Drainage in abdominal and pelvic surgery, 323; in cerebral surgery, 657; of the pulmonary cavity, 302.
Drainage-tube, flexible catheter as a, 102.
Drake, Dr. Daniel, a letter of, written forty years ago, 124.
Drew, Dr. C., Florida as a resort for consumptives, 54; the climate of Florida, 279.
Drinking habits and longevity, 185.
Drowning, phenomena of death by, 212.
Drugs, percentage of useful, 135; that live, 677; useless, multiplication of, 629.
Drum-head and ossicles, excision of, for disease of the tympanic attic, 329.
Drum-membrane, partial calcification of, 39.
Drzewiecki, Dr. Joseph, some remarks on the treatment of pleurisy by salicylate of soda and salol, 205.
Dulles, Dr. Charles W., notice of book by, 516.
Dunphy, Dr. John F., death of, 188.
Duodenal ulcer, diagnosis of, 609.
Duodenostomy and gastro-enterostomy, 156.
Dutch steamship line, medical service on the, 54.
Dying, the sensations of the, 451.
Dysentery, naphthalin enemata in, 308.
Dysmenorrhœa, membranous, electricity in, 62; oxalate of cerium in the treatment of, 12; treatment of, 692.
Dyspepsia, as reflected in the mucous membrane of the upper air-passages, 357; idiopathic, 565; cardiac, 565.
Dysphagia with dilatation of the œsophagus, 751.
Dystrophies, muscular, 351, 599.
Dystrophy, subcutaneous connective-tissue, of the arms and back, 350.

E

Ear, ceruminal accumulations in, 443; contribution to the anatomy of the elephant's, 101; disease, nasal difficulties in, 330; foreign body in the, for eighteen years, 182; insane, 600; middle, diseases of the, 464; neurosis of, resembling coryza sympathetica, 336; polypoid angioma of, 101; purulent inflammation of the middle, nystagmus in connection with, 102; seborrhœa of, 445; tubercular disease of the, 424.
Eclampsia, puerperal, 323.
Ectocardia, 156, 163.
Edes, Dr. Robert T., a case of cerebral tumor, 89; the Congress of American Physicians and Surgeons, 278.
Edson, Dr. Benjamin, a case of pneumonia with delayed resolution—abscess opening externally—recovery, 421.
Edson, Dr. Cyrus, a new vaccinator, 719.
Education in relation to health, 580.
Edwards, Dr. William A., notice of book by, 516.
Egan, Dr. P. R., antipyrin as an analgesiac, 477.
Eichberg, Dr. Joseph, pure air in pneumonia, 604.
Einhorn, Dr. Max, a case of dysphagia with dilatation of the œsophagus, 751.
Elbow-joint, excision of, 320; injury of, involving the ulnar nerve, 601; loose body in the, 211.
Electric light in surgery, head-lantern for the employment of, 100.
Electric prostration, 705.
Electrical currents, alternating, experiments with, 160.
Electrical properties of the human heart, 538.
Electrical terms, mnemonics of, 220.
Electricity, death by, 623, 678; death-currents of, 130; definition of terms employed, 61; execution by, 597; in ascites, 702; in gynecology, 61; in the vomiting of pregnancy, 563.
Electrolysis, 331; in angioma and goitre, 303; in gynecology, some details in the management of, 373; in stricture of the rectum, 303; in the treatment of uterine fibroids, 10, 102, 191, 253, 555; in urethral stricture, 24, 210, 327, 539, 633.
Electro-motive force, definition of, 61.
Electro-therapeutics, clinical notes on, 695; in gynecology, a new method of, 374.
Elements of physiological psychology, book notice, 518.
Ellis, Dr. R., treatment of insolation, 148.
Embolism of the central retinal artery, 137.
Embryotomy with Braun's hooks, 731.
Emerson, J. M., notice of book by, 132.
Emetic, urine as an, 690.
Empedocles as a bacteriologist, 720.
Emperor Frederick, report of the post-mortem examination on the body of, 130.
Emphysema, 496.
Empyema, double primary, 177; of the gall-bladder and its surgical treatment, 67; surgical treatment of, 301.
Endometritis, injections of nitric acid in, 323.
Endoscopic apparatus, recent improvements in, 658.
Engelsman, Dr. B., deaf-mutism; its pathology, causes, and treatment, 533.
English, Dr. D E., cholera infantum and diarrhœa, 165; quinine and the tariff, 194.
Enteroptosis, 538.
Enterostomy for acute intestinal obstruction, 233.
Enuresis, treatment of, by white sumac, 592.
Epidermal hypertrophies, treatment of, 28.
Epididymis, primary cancer of, 349.
Epiglottis, angioma of, causing hæmoptysis, 83; new method of raising the, 603, 611.
Epilepsy, associated with insanity, 143; focal, treated by trephining and excision of the motor centre, 351; following cerebral hemiplegia, 328.
Epileptiform attacks from a cerebral tumor, 89.
Epiphysis, superior tibial, traumatic separation of, 241.
Epistaxis, oleum origanum in, 591.
Epithelioma of the body of the uterus, 655.
Erosion of carbuncle, 29, 48.
Erethism, vesico-urethral, in locomotive engineers, 495.
Ergot in arresting hemorrhage, 683; in obstetric practice, 750.
Erlich's test, 684.
Erysipelas, mechanical treatment of, 247; Nussbaum's treatment of, 565; of the larynx, 418; sticking-plaster treatment of, 72; treatment of, 711.
Essentials of chemistry and toxicology, book notice, 516.
Ether, new use for, during anæsthesia, 636; or chloroform anæsthesia, 652.
Ethylate of sodium in the treatment of nævus, 663.
Eucalyptol as a disinfectant of air, 166.
Euthanasia, 757.
Evacuator, perfected, for removal of débris from the bladder, 350.
Evolution, pyrexia in relation to, 81.
Excellent sentiment but poor surgery, 608.
Excision of the knee-joint, 380.
Excisions of the larger joints, 319.
Execution by electricity, 597.
Exercise without fatigue in the treatment of pulmonary tuberculosis, 7.
Exophthalmic goitre, 464.
Exophthalmus, pulsating, cured by ligation of the common carotid artery, 135.
Expectorants, use of, 685.
Extension apparatus, a new, 111.
Extension-windlass method of treating fractures of the long bones, 169.
Extra-uterine fœtation, destruction of the fœtus by the galvanic current without interruptions, 49; primary laparotomy for, 50; uninterrupted galvanic current in, 110.
Extroversion of the bladder, 68.
Eyeball, evisceration of, Mules' operation for, 484.
Eye, mycotic affections of the, 434.
Eye-symptoms, value of, in the localization of cerebral disease, 687.
Eyes, congenital absence of both, 420.

F

Falsetto voice, cure of, 381.
Fat people, rules for, 562.
Fecal matter, common slag as a deodorizer of, 72.
Fecundation, artificial, a curious account of, 195.
Fee, a noble, 701; perplexingly uncertain, 691.
Fees, classification of, 511.
Feet, sweating of the, 419.
Fehling's method of testing for sugar, 84.
Fel bovis inspissatum as an antipyretic, 88.
Felons, ointment of the nitrate of mercury in, 564.
Femur, fracture of, treatment by the extension-windlass method, 169; intracapsular fracture of the neck of, 732; treatment of ununited fracture of the neck, 546.
Fever, 359; and the heat-regulating apparatus, experiments in the study of, 42; ox-bile in the reduction of, 88.
Fibro-myomata complicating pregnancy and labor, treatment of, 394.
Fibroid tumor, hysterectomy for, 714.
Fibroids, uterine, 371; abdomino-vaginal hysterectomy for, 181; treatment of, by Apostoli's method, 10, 102, 191, 253, 555.
Fieuzal, Dr. J., death of, 216.
Filaria sanguinis hominis, history of, 349.
Filariosis, 593.
Finger-nails, accident from biting the, 125; furrows on the, 419.
Finger, supernumerary, 76.
Fischer, Dr. Harris, a synopsis of treatment in twenty-six cases of pneumonia occurring consecutively in a miscellaneous practice, 93.
Fischer, Dr. Louis, epistaxis, its treatment by oleum origanum, 591.
Fischer's method of testing for sugar, 84.
Fish, parasites in, 208.
Fisher, Dr. C. H., adjustable frames for taking facial measurements, 522.
Fissure of the cervix uteri, 565.
Fistula in ano, treatment of, 139.
Flap-splitting, Tait's method of, 48.
Flat-foot, observations on seventy-five cases of, 355.
Floating kidney, a frequent trouble in women, 486.
Floating spleen, splenectomy for, 639.
Florida as a resort for consumptives, 54, 166, 279.
Flint, Dr. Austin, a case of sciatica treated with large doses of antifebrin, 646.
Fluorescine in the diagnosis of corneal lesions, 733.
Fly, the, as a carrier of disease, 245.
Fœtus, development of the, 647; infection of through placenta, 620.
Fœtation, extra-uterine, 372; destruction of the fœtus by the galvanic current without interruptions, 49; primary laparotomy for, 50.
Food adulteration and its detection, book notice, 517.
Food, indigestible, a plea for, 708; of American and European laborers, 623.
Foods, artificial, composition of, 167.
Foot and shoe, 319.
Foot-ball pathology, 538.
Foot-ball players, injuries of, 637.
Foramen ovale, patent, 436.
Foreign body in the ear for eighteen years, 182.
Forest, Dr. W. E., the mnemonics of electrical terms, 220.
Foster, Dr. B. D., hysterical spasm of the œsophagus in a young child, 66.
Fothergill, Dr., an interview with the late, 524.
Fothergill, Dr. J. Milner, death of, 45, 73.
Fowler, Dr. E. S., King's pocket operating and amputating case, 40.

Fracture, old, of the arm, enormous tumor at the seat of, 657; ununited, of the neck of the femur, treatment of, 536.
Fractures of the long bones, extension-windlass method of treating, 169.
Freckles, removal of, 542.
Freeman, Dr. J. N., death of, 272.
Freiburg, study of gynecology in, 193.
French, Dr. William Freeman, a ranula caused in a very peculiar manner, 507.
French Surgical Society, 189.
Fright, death from, 65.
Frost-bites, potassium permanganate in, 196, 552.

G

Gall-bladder, empyema of, and its surgical treatment, 67.
Gall-stones, forty-three passed by a child, 580; multiple, in the liver, 571; raspberry seeds mistaken for, 456; treatment of, by olive-oil, 27.
Galvanic current, uninterrupted, in extra-uterine fœtation, 110.
Galvano-cautery handle, 521.
Ganglion-cells, histological changes produced in, by stimulation, 338.
Gangrene, of the lung, incision of, 593, 601; spontaneous, of the scrotum and sheath of the penis, 649; traumatic, 460.
Gardinier, Dr. Herman C., case of double primary empyema, with recovery, 177.
Garnett, Dr. A. Y. P., obituary of, 74.
Gastric affections, diagnosis of, 496.
Gastro-enterostomy, 156; and cholecystenterostomy, 513.
Gastro hepatic diseases, therapeutic value of mineral waters in, 358.
Gastrostomy, 303; in cancer of the œsophagus, 165.
Gaultheria, toxic dose of the oil of, 96.
Geddings, Dr. W. H., aseptic climates without altitude, 726.
Gelsemium, utility of, 563.
General practitioner, field of the, 428.
Genito-urinary organs, surgical diseases of, including syphilis (book notice), 132.
Genito-urinary surgery, progress in, 107.
German Emperor, medical case of the, 520.
German surgeons, report of, in the case of the late Emperor Frederick, 42, 45.
Germicidal action of peroxide of hydrogen, 243.
Gestation, ectopic, 715.
Gibney, Dr. V. P., chronic joint diseases and constitutional treatment, 472.
Gifford, Dr. H., notes on the germicidal action of peroxide of hydrogen, 243.
Gilliam, Dr. D. Tod, removal of the uterine appendages, with unfavorable sequelæ—two illustrative cases, 389.
Glaucoma, 433; is astigmatism a factor in the causation of? 352.
Glioma, increased ocular tension in, 138.
Glycerine enemata, purgative action of, 495.
Glycosuria from salicylic acid, 307.
Goat, the, *vs.* the cow, 70.
Goelet, Dr. Augustin H., dilatation of the cervix uteri *vs.* divulsion, 588.
Goitre, ligature of the thyroid arteries in, 211; unique case of, 739.
Gold, "dynamic" compounds of, 402.
Goldenberg, Dr. H., urinary examination in localizing gonorrhœa, 700.
Gonorrhœa, clinical observations on, 326; in women, the consequences of, 43; localization of, by urinary examination, 700; pyæmia as a direct sequel of, 325; spinal manifestations of, 587; therapeutics of, 552.
Gonorrhœal rheumatism, a point in the diagnosis of, 270.
Goodell, Dr. William, antipyrin in sea sickness, 633.
Gordon, Dr. S. C., a review of some points in gynecology, 385.
Gout, and tuberculosis, 42; chronic, 47; in a youth of fifteen years, 182: milk diet in, 168.
Gouty urethritis, 573.
Graduates from medical colleges, percentage of incompetent, 426.
Grandiflorine, 27.
Grandin, Dr. Egbert H., electricity *vs.* laparotomy in inflammatory affections of the uterine appendages, 204.
Gravel, new remedy for, 28.
Graves' disease, climate as an etiological factor in, 337.
Green, Dr. C., the catheterization of women, 277.
Griffin, Dr. E. Harrison, nervousness produced by obstruction of the nares, with reports of cases, 65.
Guaiacol in phthisis, 156.
Gums, red line on the, suggestive of pulmonary tuberculosis, 539.
Gunshot wounds of the abdomen, 25.
Gynecology, electricity in, 61; review of some points in, 385.

H

Hadra, Dr. B. E., abdominal neurosis and exploratory laparotomy in the male, with cases, 63.
Hæmatoma oris as a sign of injury to the spine in the superior cervical region, 379.
Hæmato-mediastinum, 536.
Hæmoglobinuria, and rheumatism, 41, 155; diagnosis of, 162.
Hæmophilia and circumcision, 224.
Hæmoptysis, angioma of the epiglottis causing, 83.
Hæmoptysis, iodoform in, 549, 654.
Hæmorrhoids, Whitehead's operation for, 29, 47.
Hæmostatic, pengawar djambi as a, 74.
Hall, Dr. C. H. H., clinical notes on electro-therapeutics, 695.
Hammer-toe, 189.
Hansen, Dr. C. M., a case of acquired atrophia uteri, 422.
Hare, Dr. H. A., notice of book by, 132.
Harelip, cocaine used in operating for, 479.
Hart, Dr. B. F., mistaken diagnosis, perhaps, 606.
Harvey, Dr. John G, cure of hernia by injection, 291.
Hawes, Dr. John B., hospital notes in Bohemia, 109.
Hay fever, as a disease of central nervous origin, 32; contribution to the study of, 641; spinal ice-bag in the treatment of, 34.
Hayap, a new local anæsthetic, 745.
Headache, migranous, treatment of, 308; sightseer's, 481.
Headaches, so-called congestive, dependent upon abnormal conditions of the nasal passages, 200.
Health, education in relation to, 580.
Health-resorts, Florida, 54; in Australia (book notice), 132; the Riviera, 53; *vs.* institutions for the treatment of pulmonary consumption, 337.
Healthfulness of our country and the statistics of an exceptionally healthy city, 568.
Heart, and aorta, a peculiar substance found in the, 703; cyst in the, 509; development of the ventricular valves and walls of the, 339; disease, danger of blistering in, 747; successful pregnancy in, 590; electrical properties of the human, 538; failure, caffeine in, 74, 308; failure, sodium chloride in, 308; failure, sudden, in diphtheria, 574; fatty, 316; movable, 528; rhythm, disturbances of, with reference to their causation and their value in diagnosis, 342; rupture of the, 571; tonic, neriatin as a, 99; treatment of chronic affections of, 293; treatment of valvular affections of the, 343; troubles, organic, and marriage, 81; weak, and its treatment, 755; weak, as affected by climate and temperature, 383.
Heat, bodily, the etiology and pathology of, in relation to disease, and the use of antipyretics, 85; centres in man, 327; radiation, new facts as to, 80.
Helleborein as a local anæsthetic, 216.
Hematocele, intraperitoneal, with suppuration, 347.
Hemianopsia, bitemporal, caused by aneurism of an anomalous artery, 377.
Hemi-chorea coming on after parturition, 509.
Hemiparesis from a cerebral tumor, 89.
Hemorrhage, carotid, successful treatment of, 563; ergot in, 683; progressing cerebral, management of, 666, 683; pulmonary, treatment of, 651; uterine, electricity in, 62; internal, elastic ligatures of the limbs for, 580.
Henry, Dr. Morris B., the organization of the Roosevelt Hospital, 740.
Hepatic disease, premonitory signs and treatment of, 41.
Heredity, 275.
Hernia, cure of, by injection, 291: etiology of, 434; of the testicle, 446; radical treatment of, 141, 213, 316, 544, 688; strangulated inguinal, 76; umbilical, rupture of, 370.
Heterophoria, tenotomy for the correction of, 352.
Hiccough, 456.
Hinde, Dr. Alfred, two cases of intranasal disease, 145.
Hip-disease, fixation and traction in, 380; from an unusual cause, 592.
Hip-joint, excision of, 320.
Hippocrates on various diseases, 222.
Hoagland Laboratory in Brooklyn, 712.
Hoarseness, treatment of some forms of, 381.
Hofheimer, Dr. J. F., report of a case in which an atomizer-tip was forced down a patient's throat, dislodged, and swallowed, and finally passed per rectum, 64.
Hofmeister on diabetes, 14.
Holden, Dr. Ward A., a case of congenital absence of the iris with cataract, dislocation of one lens, nystagmus, and strabismus, 147.
Holliday, Dr. W. Z., a case of obstruction of the bowel; one thousand watermelon seeds removed from the anus, 508.
Homatropine hydrobromate as a mydriatic for determining errors of refraction, 290.
Homicidal paranoia, and the Whitechapel murderer, 427; in Texas, 453.
Hope, Dr. George B., some clinical features of diphtheria and the treatment by peroxide of hydrogen, 446.
Horse-flesh, 662.
Hospital notes in Bohemia, 109.
Hospital risks in St. Petersburg, 551.
Hospital Saturday and Sunday Association, 540.
Hospitals Medical Society of Paris, 162.
Hospitals, public, management of, 412.
Hot-air, controversy concerning the use of, in phthisis, 570; in phthisis, 693.
Hot-water clyster as a diuretic, 96.
Howard, Dr. Benjamin, a new and only way of raising the epiglottis, 611.
Howe, Dr. W. A., tic douloureux of seventeen years' standing treated by neurectomy, 179.
Hubbard, Dr. George E., the local treatment of diphtheria by Vleminck's solution or sulphuret of calcium, 703.
Hubbard, Dr. Le Roy W., some suggestions concerning the prevention of chronic joint disease in children, 558.
Huddleson, Dr. John T., death of, 296; the oldest living graduate of the University of Pennsylvania, 98.
Hudnut, Dr. Frank P., cocaine used in operating for single harelip, 479; prolapse of the rectum existing for twenty years, 590.
Hudson County Medical Association, 130.
Hudson, Dr. A. T., whiskey not an antidote to rattlesnake poison, 479.
Human blood, diagnosis of, 127.
Humerus, treatment of fracture of the lower end of, 23, 721.
Humphrey, Dr. Holman S, carbo-oxygen in consumption and other forms of wasting disease, 560.
Husson, Dr. F. C., an improved sponge-holder, 522.
Hutton, Dr. T. J., traumatic amputation of

leg, stump undressed for eight days, recovery, 155.
Hyde, Dr. James Nevins, notice of book by, 132.
Hydramnios, pathogenesis of, 496.
Hydrocele, corrosive sublimate as a promoter of adhesive inflammation in the radical cure of, 604; treatment of, 44, 162.
Hydrochloric acid, free, the new test for, 41.
Hydrofluoric-acid vapors, inhalation of, in phthisis, 247.
Hydrogen-gas test, 651.
Hydrogen peroxide, germicidal action of, 243.
Hydronephrosis and various complicating lesions, with ulceration into the lung tissue and discharge of fluid through the bronchi, 287.
Hydrophobia, an entire family affected with, 270.
Hydrophobine, 16.
Hymen, imperforate, 704.
Hyoid bones of some ancient Pueblo Indians, 340.
Hyperpyrexia, cause of death in, 70.
Hypertrophic growths, salicylic acid in, 332.
Hypnotic, sulfonal, a new, 416.
Hypnotism, at Berlin, 709; emotive phenomena in, 82; the new, 187.
Hypodermic medications, 717.
Hysterectomy, abdomino-vaginal, for uterine fibroids, 181; for fibroid tumor, 714; vaginal, technique of, 347.
Hysteria, abdominal pressure in, 643; in a mare, 690; in the negro, 39; in its surgical relations, 755.
Hysterical eye symptoms, 208.
Hysterical spasm of the œsophagus in a young child, 66.
Hysterorrhaphy in uterine displacements, 576; the new operation for displacements of the uterus, 756.

I

Ice-bags, spinal, in hay fever, 34.
Ice-cream poisoning, 748.
Idiocy, classification and cause of, 427.
Imagination, power of the, 221.
Immunity, acquired, 648.
Imperforate hymen, 704.
Indians, consumption among the, 383.
Indigence as a cause of high death-rates, 409.
Indigestible food, a plea for, 708.
India, climate of, 242.
Inebriates, should they be punished for crime? 473.
Inebriety, sugar-sticks for, 74.
Infancy, constipation in, 620; tuberculosis in, 251.
Infant, acute phthisis in an, 133; athetosis in an, 95; feeding, 463; sepsis in an, 134.
Infection, precautions against, 507.
Infectious diseases, causal therapeutics in, 316; sweating in, 167.
Inflammation, new theory of, 654.
Ingrowing nail, bloodless methods of treating, 621.
Inguinal colotomy for malignant disease of the rectum, 706.
Inhalations in lung disease, 300, 621, 693.
Insane, psychical treatment of the, 468.
Insanity, epilepsy associated with, 143.
Insolation, treatment of, 148.
Insomnia, hints for the treatment of, 664; self-asphyxiation in the treatment of, 495; uræmic, pilocarpine in, 661.
Inspired air, changes in the, in passing through the nose, 580.
Instruments, how shall the doctor disinfect his? 452.
Intercolonial Medical Congress, 625.
Intermittent fever, urine after, 521, 619.
International Congress of Ophthalmology, 431.
Interpleural pathological products, 525.
Intestinal diseases of infancy and childhood, book notice, 516.
Intestinal invagination, peculiar case of, 692.
Intestinal obstruction, acute, 309; acute, enterostomy for, 233; from worms, 182; laparotomy for, 601; electrical treatment of, 593.
Intestinal perforation, hydrogen-gas test of, 651.
Intestine, gunshot wounds of the, laparotomy for, 595; resection of, 161, 190; complicated operation on the, 83.
Intracranial lesion, 490.
Intracranial vessels, tongue as a guide to the diagnosis of lesions of, 158.
Intranasal disease, two cases of, 145.
Intranasal hypertrophies, mild measures in the treatment of, 382.
Intranasal obstructions, 405.
Intrapleural injections of sterilized air for pleuritic effusion following pneumothorax, 395.
Intubation of the larynx, abandonment of, at Leipzig, 399; foreign estimate of, 400; substitute for, 336.
Invagination, intestinal, peculiar case of, 692.
Iodism, 737.
Iodoform, in hæmoptysis, 549; poisoning, 270
Ipecacuanha spray in the treatment of diseases of the respiratory passages, 95.
Ireland, gynecology and obstetrics in, 191.
Irideremia, double congenital, 137.
Iris, chromatic asymmetry of the, 573; congenital absence of, 147.
Iron, uselessness of the hypodermic employment of, 424.

J

Jackson, Dr. George Thomas, some dermatological don'ts, 754.
Jacobi, Dr. A., notice of book by, 516.
Jamaica-ginger inebriates, 758.
Jaundice, 305; catarrhal, treatment of, 174: epidemic of, at Glasgow, 756.
Jaw, anchor splint for fracture of the, 420.
Jewett, Dr. Harvey, death of, 400.
Johnson, Dr. George, notice of book by, 516.
Johnson's method of testing for sugar, 84.
Joint disease, chronic, in children, prevention of, 558; chronic, rest in the treatment of, 281; immobilization in, 380; and constitutional treatment, 472, 491; and injuries, operative and mechanical treatment of, 380.
Joints, erosion of, 687.
Jones, Dr. C. Handfield, observations on inflammatory and certain other changes in the minute vessels of the pia mater, 197.
Josephi, Dr. S. E., to facilitate catheterization in women, 195.
Journalism, ethics of, 541.

K

Kakeles, Dr. M. S., an interesting case of strangulation of a portion of the ileum through an opening in the meso-rectum, probably of a congenital nature, 702.
Keating, Dr. John M., notice of book by, 516.
Kellogg, Dr. Abner O., death of, 429.
Keloid, resorcin in the treatment of, 649, 733.
Kentucky State Medical Society, 103.
Keratosis obturans, 445.
Kerosene, poisoning by, 64.
Keyes, Dr. E. L., notice of book by, 132.
Kidney, acute parenchymatous inflammation or degeneration of, 108; anomalous location of, 12; cancer of, without urinary symptoms, 503; dermoid cyst of the, 108; disease of the, etiology of, 319; movable, truss for, 635; operations on the, 375; phthisis of one, and hydronephrosis of the other, 22; primary tuberculosis of the, 571; syphilis of, 162; tuberculous, removal of, 297; uric acid, calculi of the, 456.
Kidneys, conditions which precede serious lesions of the, 465; contusions and lacerations of, 466.
Kilcher, Dr. Karl, death of, 129.
King's clamp in the treatment of varicocele, 12.
King's pocket operating and amputating case, 40.
Kinnear, Dr. B. O., hay fever as a disease of central nervous origin, with a few cases successfully treated in accordance with the hypothesis set forth, 32.
Kinnier, Dr. J. D. F., epilepsy associated with insanity, 143.
Kitchen, Dr. J. M. W., a contribution to the study of hay fever, 641.
Kittrell, Dr. R. N., treatment of catarrhal jaundice, 174.
Knee-jerk, nature of the, 361.
Knee-joint, anchylosis of, subcutaneous operation for, 370; excision of, 320, 380; non-febrile purulent effusion of, in an infant, followed by ophthalmia, 23; operation for anchylosis of, resulting in gangrene, 478.
Kolpo-cystotomy, 118.
Kolpo-uretero-cystotomy, 120.

L

Labor, fracture of the symphysis pubis during, 590; indications for artificial aid in, 346; induced, 346; pains, antipyrin for the relief of, 557; pilocarpine in, 618; posture in, 675; third stage of, management of, 192.
Lacerations of the cervix, the harmlessness of, 44.
Lachrymation, treatment of persistent, 432.
Lactic acid as a caustic, 52.
Ladd, Dr. George T., notice of book by, 518.
Language of medicine, book notice, 517.
Lanolin and boric acid in the skin diseases of children, 542, 690.
Laparotomy, conclusions from a second series of one thousand consecutive cases of, 553; exploratory, in chylous ascites, 189; exploratory, in the male, 63; for gunshot wounds of the intestine, 595; for intestinal obstruction, 601; for peritonitis, 45, 107; mortality of, 705; primary, for extra-uterine fœtation, 50.
Largest woman in the world, death of, 570.
Laryngeal enchondroma, subglottic, 382.
Laryngeal image, photographic study of, in the singing voice, 357.
Laryngeal phthisis, menthol in, 712; residence in high altitudes as a means of cure of, 336.
Laryngology, report on, 106.
Larynx, cancer of the, 509; cancer of, results of treatment of, 16; cortical motor centre for, 336; erysipelas of the, 418; partial extirpation of, 167; stricture of, 335; subglottic stenosis of, treated by dilatation, 335; total extirpation of, 190.
Lateral curvature, early diagnosis and rational treatment of, 488; early treatment of, 380; etiology of, 317.
Lavies, Dr. J. S., death of, 633.
Laymen in medical positions, 598.
Lead-poisoning, a new cause for, 450; from glazed earthenware, 537.
Lean people, rules for, 562.
Leaming, Dr. J. R., interpleural pathological products; their cause, significance, and specific relationship to pulmonary phthisis, 525.
Leçons sur les maladies du système nerveux, book notice, 517.
Left-handedness, 28.
Legros, Dr. Ch., notice of book by, 517.
Lens, calcareous, extraction of partially absorbed, complicated by synechia posterior, with resulting vision of $\frac{20}{20}$, 390; dislocation of, complicating aniridia, 147; partially absorbed calcareous, extraction of a, 138.
Leper settlement on the Island of Molokai, 269.
Lepra nervorum, 285.
Leprosy, in India, 679; nerve stretching in, 303.
Leptomeningitis with symptoms of disseminated sclerosis, 377.
Leslie, Dr. M. S., artificial cold for yellow-fever hospitals, 608.
Lester, Dr. F. H., death from fright, 65.
Letter, Dublin, 191; Freiburg, 193; London, 80, 164, 491, 519, 601, 632, 687, 739; Paris, 25, 53, 81, 164, 437, 492, 520, 603, 717.
Leucocythæmia, chicken-blood in, 440; splenic, 75; stone in the bladder in connection with, 376.

Leuf, Dr. A. H. P., a flexible scalpel, 522; the injuries of foot-ball players, 637.
Levis, Dr. R. J., the influence of the climate of Florida on consumptives, 166.
Leviseur, Dr. Frederick J., a new method of studying the peculiarities of color in skin diseases, 506.
Lichen ruber and lichen planus, 355, 378.
Life insurance, the relation of medical men thereto, 20.

Light, intense, pathological results of working in, 98.
Lindley, Dr. Walter, compressed air below the sea-level, 242.
Lineæ albicantes in typhoid fever, 162.
Litholapaxy in male children, 350.
Lithotomy, hypogastric, 39.
Lithotrity, perineal, 376.
Liver, abscess of the left lobe of the, evacuated by incision into the abdominal wall, 704; abscess of, with perforation of the diaphragm, 78; diagnosis of diseases of, 461; disease of, premonitory signs and treatment of, 41; enlargement of, in rickets, 247; multiple gall-stones in the, 571; sewing up the, 16.
Lloyd, Dr. Jordan, inflammation of the seminal vesicles, 521.
Localizations, special sense, in the cortex cerebri of the monkey, 113.
Lockwood, Dr. J. F., acrania, 181.
Locomotor ataxia, persistent diarrhœa in, 40; symptoms of, in a case of arsenical paralysis, 124.
Longevity, and drinking habits, 185; heredity and temperament as factors in, 196; in New England, 709.
Louisiana Medical Society, 96.
Loving, Dr. Joseph, death of, 757.
Lowrey, Dr. M. G., circumcision by maternal impression, 718.
Lowry, Dr. Isabel, the therapeutical value of mineral waters in the diseases of childhood, 149.
Lumbar colotomy, 68.
Lunatic, murder by a, 398.
Lung, gangrenous, incision of, 593, 601.
Lung test, inefficiency of Zaleski's chemical, 95.
Lupus, atypical varieties of, 250.
Lynch, Dr. D. W., constriction of the penis by an iron ring, 155.
Lynch, Dr. John S., death of, 570.

M

McManus, Dr. James, the use of large doses of calomel in pneumonia, 260.
McTaggart, Dr. M. F., the vaginal tampon, 493.
Mackenzie controversy, 510, 625.
Mackenzie, Sir Morell, and Professor Virchow, 712; and the report of the German physicians, 187.
Malaria, and diabetes, 747; eruptions of the skin occurring during the course of, 674; in a dog, 646; study of, at Rome, 412.
Malarial diseases, mineral waters in, 358.
Malarial fever and tuberculosis, antagonism between, 218.
Malarial pigment, 436.
Malarial retinal hemorrhage, 36.
Malgaigne's hooks, antiseptic use of, in transverse fracture of the patella, 503.
Malignant tumors, recurrence of, 690.
Malingering, curious case of, 307.
Maloney, Dr. J. A., a study in physiological acoustics—preliminary notice, 589.
Mammary glands, inactive, atrophy of the, 647; absence of, 188.
Man, physical perfection of, 666.
Manikins, physiological, 73.
Manual for hospital nurses, book notice, 517.
Mare meat, 662.
Marine Hospital Service, 679.
Marriage, and heart disease, 81; late, evil consequences of, 318; limiting, 598.
Mastitis, sculptor's clay in, 439.
Mastoid disease, in Minnesota, 190; pachymeningitis, and multiple cerebral abscesses, 436.
Masturbation and stricture, connection between, 326.
Maternal impressions, 607; and hare-lip, 746; and the sex of the fœtus, 216; circumcision by, 718; supernumerary nipple associated with, 479.
Matthews, Dr. J. M., some obscure affections of the rectum, 528.
Maycock, Dr. Burt J., a peculiar substance found in the heart and aorta, 703.
Mays, Dr. Thomas J., notice of book by, 518.
Measles, contagion of, 649.
Meat, the smell of, 747.
Mechanical treatment of erysipelas, 247.
Meco-narceine, 196.

New York Post-Graduate Hospital, 757.
New York State Medical Association, 450, 454, 487.
Nice, sanitary condition of, 585.
Nilsen, Dr. J. R., splenectomy for floating hypertrophied spleen, 639.
Nipple, supernumerary, associated with maternal impression, 479.
Nitro-glycerine in tinnitus aurium, 509.
Nitrous oxide anæsthesia, first case on record, 454.
Norderling, Dr. K. A., penghawar djambi not a new hæmostatic, 478; poisoning by kerosene, 64.
Nose, changes in the inspired air in passing through the nose, 580; primary carcinoma within the, 146.
Nosebleed, death from, 737.
Nosography, discussion on, 455.
Nostrils, convictions regarding the, in respiration, 698.
Novy, Mr. Frederick S., notice of book by, 518.
Nursing mothers, medicines that can be safely given, 97.
Nutritive processes, influence of the nervous system on the, 544.
Nystagmus, complicating aniridia, 147; in connection with purulent inflammation of the middle ear, 102.

O

Obesity, diet in, 562; water and, 190.
Obstetric practice, ergot in, 750.
Obstetrics, the importance of practical, in the course of instruction given in the medical schools, 627.
Obstruction, acute intestinal, 544; biliary, fever accompanying, 461; of the bowel by water-melon seeds, 508.
Odium medicum, 744.
Œdema neonatorum and phlegmasia alba dolens, 268.
Œdema, sub-epiglottic, in a diabetic patient, 336.
Œsophagotomy, internal, 356.
Œsophagus, cancer of, gastrotomy in, 165; deficient, 705; dilatation of, with dysphagia, 751; hysterical spasm of, in a young child, 66.
Ohm, definition of, 61.
Ohm's law, 61.
Old age, treatment of bronchitis in, 13; treatment of coxitis of, 356.
Oleander as a heart tonic, 99.
Olive-oil in the treatment of gall-stones, 27.
Oliver's test for bile in urine, 140
Onimus, Dr. E., notice of book by, 517.
Ontario Medical Association, 18.
Oöphorectomy, influence of upon the sexual appetite, 129, 194.
Oöphoritis, subacute, 77.
Opacities, membranous, in the vitreous, surgical treatment of, 238.
Ophthalmia, Egyptian, influence of flies in the production of, 433; tea-leaf poultices, 417.
Ophthalmology, importance of bacteriology in, 434; progress in, 103; Seventh International Congress of, 431.
Ophthalmometer of Javal and Schiotz, 136.
Ophthalmometry, 431.
Ophthalmoplegia externa, 545.
Opium habit, causes and prevention of, 627.
Opium-smoking, 692.
Optic neuritis, monocular, 353.
Osler, Dr. Wm., appointment of, at Johns Hopkins University, 454; has the mortality in pneumonia increased? 604; on the diagnosis of duodenal ulcer, 609.
Osteotomy, femoral, 356; for anterior tibial curves, 356.
Ostrom, Dr. H. I., the vaginal tampon, 280.
Othæmatoma, or insane ear, 600.
Otitis, chronic suppurative, with metastatic irido-choroiditis, 329; externa circumscripta, 441; externa desquamativa s. exfoliativa, 442; externa diffusa, 442; media from the use of the nasal inhaler, 152; media suppurativa, boracic acid solution in, 330.
Ouabaine, 744.
Ould, Sir Fielding, distichs upon, 192.
Ovarian cyst, and cirrhotic ovary, 77; suppurating, in a child, 76.
Ovarian tumor, ascites simulating, 687; congenital, 648; suppurative, cured after spontaneous rupture, 675; in pregnancy, 293.
Ovaries, blood calculi in the, 683; influence of removal of, on the sexual feelings, 129, 194.
Ovariotomy, lessening the dangers of, 492; rupture of the colon following, 655; second, on the same patient, 347.
Ovary, cirrhotic, 77.
Overcrowding of the medical profession, 246.
Ox-bile, as an antipyretic, 88.
Oxalate of cerium in dysmenorrhœa, 12.
Oxaluria, especially in its relation to uric acid, 665, 681.
Oxygen, in the capillary bronchitis of children, 618; not so important in respiration, 680.
Oxy-propylen-di-iso-amylamine, 662.

P

Pack, cold, as an antipyretic, 88.
Packard, Dr. Charles W., was it metastatic rheumatic peritonitis? 749.
Paddling, the dangers of, 159.
Palate, soft, chorea of the, 403.
Pancreas, accessory, in the wall of the duodenum, 571; alterations of, relations of diabetes mellitus with, 25; diagnosis and successful removal of a cyst of the, 16; removal of cyst of, 16.
Papilloma, laryngeal, 381; relation of, to syphilis and tuberculosis of the skin, 354.
Papoid in diphtheria, 448.
Paralysis, arsenical, with symptoms of locomotor ataxia, 124; cerebral, in children, 649; diphtheritic, 456; diphtheritic, strychnine in, 28; from pressure by a callus, 161; pharyngeal and laryngeal, due to bulbar lesions, 382.
Paraplegia of Pott's disease, trephining the spine for the relief of, 214.
Parasites in fish, 208.
Paris doctors and doctors' signs, 512.
Parker, Dr. W. Thornton, the Association of Acting Assistant Surgeons, 740.
Parturition, hemi-chorea coming on after, 509.
Pasteur Institute, opening of the, 717.
Pasteur's antirabic inoculation, futility of, 635.
Patella, surgical treatment of fracture of, 467; transverse fracture of, antiseptic use of Malgaigne's hooks in, 503.
Pathological specimens, fluid for preserving, 134.
Payne, Dr. S. M., a new instrument for demonstrating refraction, 659.
Peabody, Dr. George L., two deaths from poisoning by chlorate of potash, with autopsies, 57.
Peganum harmala, 307.
Pelvic abscess, 323, 325.
Pelvis, contracted, and the sex of the child, 664.
Pemphigus, death from, 125.
Pen ghawar djambi, a new hæmostatic, 74; not a new hæmostatic, 478.
Penis, constriction of, by an iron ring, 155.
Penzoldt's method of testing for sugar, 84.
Peppermint water in pruritus pudendi, 212.
Pepsin in surgery, 730.
Pericarditis, primary purulent, 674.
Perineum, female, anatomy, physiological functions, and methods of restoration after injury, 324; lacerated, operation for, 715; lacerated, the primary treatment of, 154; plea for the primary operation on, 48; surgical treatment of the, 324.
Periosteal swellings, acute, probably rickety, 210.
Periostitis, variolous, 411.
Peritoneum, carcinoma of the, 75.
Peritonitis, laparotomy in, 45, 107, 324; operative treatment for, 592; rheumatic, 749.
Perkins, Mr. George L., a centenarian, 160.
Peroxide of hydrogen, germicidal action of, 243; in diphtheria, 446.
Peters, Dr. John C.; Dr. Agnew and the New York Pathological Society, 742; Dr. Sands and the New York Pathological Society, 673.
Peterson, Dr. Frederick, a case of arsenical paralysis with symptoms of locomotor paralysis, 124.
Pharmacy law in New York State, 513.
Phenacetin as an anodyne, 15.
Phleboliths, 133.
Phlebo-sclerosis, 430.
Phlegmasia alba dolens and œdema of infants, 268.

gogen excreted by germs, 647.
ogosine, 654.
Phonograph, as an instrument of precision, 450; in physical diagnosis, 586.
Phosphate of copper in tuberculosis, 480.
Phthisical patients undergoing climatic treatment, management of, 383.
Phthisis, a disease of the night, 156; acute, in a young child, 133; and bad drainage, 17; and the use of alcohol, 451; arterial changes in, 390; climate of Florida in, 166; contagiousness of, 650; evidences of the curability of, 95; fresh air in, 165; guaiacol in, 156; hot dry inhalations in, 693; hot moist inhalations in, 660; indications for altitude in the treatment of, 358; inhalation of hydrofluoric acid vapors in, 247; inhalations in, 247, 621, 660, 693; pulmonary, relationship of interpleural pathological products to, 525; pulmonary, treatment of, by parenchymatous injections of creasote, 508; relative importance of different climatic elements in the treatment of, 357; tannin in, 115; treatment of, by baking, 511.
Physical perfection of man, nature of, 667.
Physicians, female in Turkestan, 758; protection for American, 755.
Physiology, essentials of, book notice, 132.
Physiology of theatrical emotion, 580.
Physiological acoustics, a study in, 589.
Pia mater, inflammatory and other changes in the minute vessels of, 197.
Piffard, Dr. H. G., loss of sexual feeling after oöphorectomy, 194.
Pilocarpine, in Bright's disease, 68; in deafness, 224; in middle-ear diseases, 397; in pregnancy, 520; in pregnancy, labor, and the lying-in state, 618.
Pituitary body, possible disease of, 299.
Placenta, double, and single pregnancy, 746; expulsion of the, 661; infection of fœtus through, 620; œdema of, 133.
Placenta prævia, case of, 714.
Placentas, two, with one child, 180.
Plethysmographic study of changes of volume in the finger and arm, produced by electrical stimulation, 359.
Pleurisy, treatment of, by salicylate of soda and salol, 205.
Pneumogastric nerve, pathology of the ganglion of the trunk of the, 181.
Pneumonia, acute lobar, 484; complicated by purulent pleurisy, and terminating in gangrene, 656; engorgement of the spleen in, 647; etiology of, 672; has the mortality of, increased? 604; its increasing death-rate—one of the essentials in its treatment, 469; large doses of calomel in, 260; mortality of, 596; mortality of, in Massachusetts almshouses, 711; open-air treatment of, 688; pure air in, 604; synopsis of treatment in twenty-six cases of, 93; treatment of, 676; with delayed resolution—abscess opening externally—recovery, 421.
Pocket-case, King's operating and amputating, 40.
Poison, general antidote for, 675.
Poisoning, by artificial mineral waters, 608; bichromate of potassium, 580; camphor, fatal case of, 578; cheese, 270; chlorate of potash, 57, 410; cocaine, acute and chronic, 480; iodoform, 270; kerosene, 64; of a regiment, 248; silver, from the prolonged application of caustic, 621.
Poisons, antagonism of, 139; organic, in respired air, 68.
Politics and insane asylums, 757.
Polymyositis, subacute progressive, 350.
Polypathy, 248.
Polyuria following fracture of the base of the skull, 66.
Pons Varolii, tumor of the, 755.
Porter, Dr. William Henry, the etiology and pathology of increased bodily heat in relation to disease and the use of antipyretics, 85.
Post-graduate instruction, the necessity of, 628.
Post-nasal punch forceps, 719.
Potassium chlorate, poisoning by, 57, 410.
Potassium permanganate in burns and frostbites, 196, 552.
Pott's disease, practical point in the treatment of, 335.
Pott's paraplegia, trephining the spine for the relief of, 214.
Poultry, tuberculous, 218.
Pouncey, Dr. J. B., an improved rectal speculum, 719.
Powers, Dr. Charles A., a contribution to the treatment of fractures at the lower end of the humerus, based on the analysis of fifty consecutive cases, 721.
Practice of medicine and surgery applied to the diseases and accidents incident to women, book notice, 516.
Practitioners' Society of New York, 47, 410, 490, 683.
Pregnancy, and operative surgery, their mutual relations, 370; double ovariotomy during, 346; extra-uterine, 78; ovarian tumors in, 293; pilocarpine in, 520, 618; scarlatina during, 734; successful, in heart disease, with spontaneous premature labor, 590; tubal, 374; vomiting of, 374; vomiting of, rectal injections of carbonic acid in the treatment of, 175; vomiting of, viburnum in, 680.
Presentation, head-downward, cause of, 566.
Preserving fluid, 134.
Prettyman, Dr. J. S., is a prolonged mercurial course advisable in syphilis? 261.
Prisms, designation of, according to their refracting power, 353.
Professional courtesy, 71.
Progressive muscular atrophy with anæsthesia, 236.
Prolapsus, suspension of the uterus for, 183.
Proprietary medicines and advertising druggists, 97.
Prostate, enlarged, at the age of forty-two, 350; hypertrophy of, operative treatment of, 348.
Prostatic obstruction, formation of an artificial urethra for, 244.
Prostatectomy, suprapubic, 395.
Prostration, electric, 705.
Prurigo, relations of, to the nervous system, 619.
Pruritus pudendi, peppermint-water in, 212.
Pryer, Dr. Wm. C., death of, 398.
Pseudo-hypertrophic paralysis, three cases of, in one family, 417.
Pseudo-kephir, 28.
Pseudo-tuberculosis, 219.
Psoriasis, iodide of potassium in, 384.
Ptomaïne-poisoning from septic meat, 745.
Ptomaïnes and gastric vertigo, 746.
Ptomaïnes and leucomaïnes, book notice, 518.
Puerperal fever, etiology of, 740.
Puerperal infections, 655.
Puerperal septicæmia, 487, 520.
Puerperal stage, scarlatina in the, 734.
Pulmonary abscess, treatment of, 536.
Pulmonary artery with two valves, 406.
Pulmonary hemorrhage, treatment of, 651.
Pulmonary phthisis, early recognition of, 251; the diagnostic significance of a red gingival margin in, 539.
Pupil, artificial, through the sclerotic coat, 738; as a guide in the administration of chloroform, 181.
Purgative action of glycerine enemata, 495.
Purpura rheumatica associated with gastric disturbances, 23.
Pyæmia as a direct sequel of gonorrhœa, 325.
Pyosalpinx, double, cured by aspiration, 617; puerperal, 436.
Pyo-thorax and pyo-pneumo-thorax, treatment of, by the seton method of through drainage, 581.
Pyrexia in relation to evolution, 81.
Pyridine, 542, 647.

Q

Quack, history of a, 176.
Quarantine and Congress, 131.
Quinine, and the tariff, 96, 194; as an antipyretic, 86.

R

Rabic poison, intravenous inoculation of, 717.
Rabies, increase of, in Paris, 164, 603.
Rabbit pest and chicken cholera microbes, 654.
Rachitis, mineral waters in, 150.

Sore throat, anæmic, 196.
Soteriology and the stomach, 653.
Sowers, Dr. Z. T., urethritis, acute cystitis, obstruction of the ureter, hydronephrosis, ulceration through the peritoneum, diaphragm, pleura, and lung tissue, and discharge of fluid through the bronchi—recovery, 287.
Sparteine, sulphate of, action of, 646.
Spasm, muscular, rhigolene for, 645.
Speculum, rectal, an improved, 719.
Spermatogenesis, 161.
Spinal abscess, treatment of, 208.
Spinal cord, degeneration of the antero-lateral ascending column, 657; operations upon, 276; removal of a tumor of, 15.
Spinal injuries, discussion on, 51.
Spinal manifestations of gonorrhœa, 587.
Spine, cervical, tumor of the, 378; injury to, in the superior cervical region, hæmatoma oris as a sign of, 379; trephining the, 214, 305.
Splanchnoptosis, 532.
Spleen, engorgement of, in pneumonia, 647.
Splenectomy, for floating hypertrophied spleen, 639; successful case of, 564.
Sponge-holder, an improved, 522.
Sponging, tepid, as an antipyretic, 88.
Starr, Dr. Lewis, notice of book by, 517.
Starr, Dr. M. Allen, apraxia and aphasia; their varieties and the methods of examination for their detection, 497.
Stavely, Dr. A. L., operation for anchylosis of the knee-joint resulting in gangrene—amputation at the thigh—recovery, 478.
Stein, Dr. Richard, a case of embryotomy with Braun's hook, 731.
Stenosis of the cervix uteri, electricity in, 62.
Stephenson, Dr. F. B., precautions against infection, 507; temperament and diathesis in disease, 614.
Sterility, one-child, 183, 636.
Sterilized air, intrapleural injections of, 307, 395.
Sterilized-milk dairy, 399.
Sternberg, Dr. George M., concerning the so-called specific germ of yellow fever, 548.
Sternum, trephining the, for pus in the mediastinum, 675.
Stertor in animals, 300.
Stethoscope, a new pocket, 578.
Stewart, Dr. Nolan, a case of uncomplicated dislocation of the carpal scaphoid bone, 423.
Stickler, Dr. J. W., incidence of scarlet fever in relation to epidemic sore throat at Bethersden, England, in 1884, produced by exposure to manure derived from cattle afflicted with aphthous fever, 10.
Stimulants (book notice), 132.
Stomach, and bowels, treatment of functional and catarrhal diseases of the, 681; diagnosis of diseases of the, 496; distention of, sudden death from, 40; sudden death from washing out, 196; ulcer of, diagnosis and treatment, 126.
Strabismus, non-paralytic, 431.
Strangulation of a portion of the ileum through an opening in the meso-rectum, 702.
Streeter, Dr. F. B., a case of recovery from traumatic tetanus, 508.
Streptococcus pyogenes found in healthy saliva, 618.
Stricture, and masturbation, connection between, 326; urethral, electrolysis in, 24, 210, 327, 539, 633; urethral, new urethrotome for, 660.

Strophanthus, advantages of, 495; as an antipyretic, 570; in the treatment of tetanus, 212.
Sugar, methods of testing for, 84; saccharin not a substitute for, 747.
Sulfonal, a new hypnotic, 416; eruption from, 623; in mental disease, 567.
Sulphur, burning, as a disinfectant, 135.
Sulphuret of calcium in diphtheria, 703.
Sulphurous-acid fumigations in whooping-cough, 215.
Sunstroke, electrical, 156; treatment of, 148.
Superfœtation, case of, 392.
Superstitions, some popular medical, 744.
Suppuration and microbes in the skin, 263.
Suprarenal capsules, disease of, without bronzing, 481.
Surgeon-General of the United States Army, report of the, 512.
Surgery, a defect in modern, 566; pepsin in, 730; points in railway, 50.
Surgical dexterity, training of the hands for the acquirement of, 541.
Surgical dressing, unglazed tissue-paper as a, 692.
Surgical mishaps, 678.
Surgical Society of Paris, 161.
Sweating, excessive, chromic acid in, 610; fetid, treatment of, 692; in infectious diseases, 167.
Sympathetic, cervical, wound of the, 674
Symphysis pubis, fracture of, during labor, 590.
Syndactylism, new operation for, 720.
Synopsis of the physiological action of medicines, book notice, 517.
Synovitis, chronic, of the knee, hot-water baths in, 537.
Syphilide, the recurrent macular, 8
Syphilis, and carcinoma, 28, 293, 424; aphasia occurring during the secondary stage of, 179; carbolate of mercury in, 26; cerebral, the mental relations of, 299; hypodermic injection of calomel in, 104; intramuscular injection of mercury in, 268; is a prolonged mercurial course advisable in?, 261; of the nervous system, 298; organisms of, small importance of, 184; renal, 162; so-called abortive treatment of, 410; specific bacillus of, 429; Zittmann's decoction in, 84.
Syphilitic conjunctivitis, 67.
Syphilitic diseases of the nervous system, prognosis of, 619.
Syphilitic infection, damages for, 399.

T

Tait, Mr. Lawson, Batley *vs.* Lawson Tait, 279; general summary of conclusions from a second series of one thousand consecutive cases of abdominal section, 553.
Tait's method of flap-splitting, 48.
Talc, powdered, in diarrhœa, 131.
Tampon, the perfect vaginal, 178; vaginal, 493.
Tannin in phthisis, 115, 168, 290.
Tape-worms, remedy for, 691.
Tar, bad effects from inhaling the vapor of, 181.
Tariff, on microscopical apparatus and scientific works, 99; on surgical instruments, 112; quinine and the, 96, 194.
Tea-leaf eye, 417.
Telephone, influence of, on the hearing power, 330.
Temperament and diathesis in disease, 614.
Temperaments, the, 128.
Temperature, increased bodily, etiology and pathology of, in relation to disease and the use of antipyretics, 85.
Tenesmus, renal, treated by kolpo-uretero-cystotomy, 116.
Terebene, observations on the use of, 383.
Testicle, clinical observations of diseases of the, 349; displacement of the, 41; hernia of the, 446.
Tetanus, cephalic, 603; hydrophobicus, 658; etiology of, 493; imitative, 112; inoculability of, 718; salicin and bromide of potassium in, 384; successfully treated with strophanthus, 212; traumatic, recovery from, 508.
Texas, climatic characteristics of, 383.
Thallin as an antipyretic, 86.
Thayer, Dr. A. L., a new extension apparatus, 111.
Thayer, Dr. William Henry, open-air treatment of pneumonia; diphtheritic pneumonia, 688.
Theatrical emotion, physiology of, 580.
Theine in the treatment of neuralgia, book notice, 518.
Therapeutics founded upon organopathy and antipraxy, book notice, 518.
Thermometer, swallowing a, 40.
Thorner, Dr. Max, a new galvano-cautery handle, 521.
Thoughts, weighing, 429.
Thrombosis, cardiac, 134.
Thymus gland, pathology of the, 369
Thyroid arteries, ligature of, in goitre, 211.
Thyroid, cancer of, 168.
Thyroid gland of the dog, 368.
Tibia, separation of the superior epiphysis of, 241.
Tic douloureux of seventeen years' duration treated by neurectomy, 179.
Tinnitus aurium, nitro-glycerine in, 509.
Tobacco amblyopia, 110.
Tobacco-smoke, influence of, upon infective micro-organisms, 567.
Toe-nail, ingrowing, 740.
Tolerance and intolerance in medicine, 628.
Tongue, as a guide to the diagnosis of lesions of the intracranial vessels, 158; as an indication of disease, 209; cancerous, removal of, 456; imaginary ulceration of the, 335.
Tonsil of the tongue, hypertrophy of, 21.
Tonsil, sarcoma of the, 381.
Tonsils, enlarged, with peculiar symptoms, relieved by the galvano-cautery snare, 405; functions and significance of the faucial, lingual, pharyngeal, and discrete, 733; growth and development of the, 593; hypertrophy of, 196.
Toothache, a remedy for, 272.
Tooth extraction, painless, 435.
Tooth, inherited deficiency of, 212.
Trachea, cancer of, 168.
Tracheotomy, and intubation, comparative methods of, in the treatment of croup, 370; substitute for, 336.
Traité d'électricité médicale, book notice, 517.
Transplantation, of mucous membrane, 212; of skin, 297; of skin from a corpse, 272.
Transudation and blood-pressure, 268.
Treatise on human physiology for the use of students and practitioners of medicine, book notice, 518.
Tremor, muscular, 377.
Trephining, for the relief of aphasia, 425; the spine, 305.
Trichinosis in New York, 160.
Tubal pregnancy, 374.
Tubercle bacilli in water, 219.
Tubercle bacillus and aneurisms, 647.
Tubercular disease, tannin in, 168.
Tubercular virus, mode of introduction and propagation of, in the economy, 250.
Tuberculosis, acute miliary, 17, 573; and gout, 42; Congress for the study of, 217, 249, 253, 461; general miliary, 572; of the lymphatics, 107; of the mucous surfaces, 217; of the vermiform appendix, 656; phosphate of copper in, 480, primary, of the kidney, 571; primary, of the uterus and tubes, 107; pulmonary, exercise without fatigue in the treatment of, 7; spread of, by the flesh and milk of diseased animals, 396; susceptibility of races of men and animals to, 249; treated by tannin, 290.
Tuberculous animals, dangers from the use of the flesh and milk of, 217.
Tuckerman, Dr. F., antipyrine in cephalalgia, 180.
Tumor, cerebral, 89; of the arm at the seat of an old fracture, 657.
Tumors, discussion on, 457; formation and classification of, 292; multiple primary, 508.
Turbinated bone, middle, a pathological condition of, 264.
Turpentine in surgery, 211.
Tuthill, Dr. Jerome, an accident from biting the finger-nails, 125.
Tympanic attic, chronic purulent inflammation of the, 329.
Tympanites, and tympanitis, 135; treated by puncture, 424.
Tynberg, Dr. S., the recurrent macular syphilide, 8.
Typhlitis and perityphlitis, surgical aspects of, 632; surgical management of, 345.
Typhoid fever, antisepsis in, 73; associated with an infective fever in cows, 409; Australian treatment of, 537; decrease of, 66; difficulties in the diagnosis of, 225, 410, 683; diminution of the number of blood-corpuscles in, 563; geographical distribution of, in the United States, 315; lineæ albicantes in, 162; magnesium salicylate in, 293; management of the stage of convalescence in, 315; some forms of paralysis after, 315.
Typhoid ulcer, perforating, propriety of surgical interference in, 345.

U

Ulcer, of the stomach, diagnosis and treatment of, 126; perforating typhoid, propriety of surgical interference in, 345.
Umbilicus, phlegmon of, 134.
Unity of the profession, and the means of procuring it, 630.
Universities, union of medical schools with, 452.
Uræmia, pathology and treatment of, modern theory of, 449.
Uræmic insomnia, pilocarpine in, 661.
Uranium salts, physiological action of, 339.
Urea, influence of bromide of potassium on the elimination of, 411.
Ureteritis in woman, 116.
Ureters in the female, palpation of, 324.
Urethra, formation of an artificial, for prostatic obstruction, 344; passage of urine and fæces by the, 541; stricture of, electrolysis in, 210, 539.
Urethral discharges, chronic, local treatment of, 326.
Urethral irritation in the male as a source of disease, 413.
Urethritis, chronic, Oberländer's views on, 326; gouty, 573.
Urethrocele, 324; distinct from cystocele, 117.
Urethrotome for close strictures of the penile uretha, 660.
Urethrotomy, dilating, for the radical cure of stricture, 375.
Uric-acid diathesis, 650.
Uric-acid, relation of excretion of, to disease, 70; relation of oxaluria to, 665, 681.
Urinary examination in localizing gonorrhœa, 700.
Urine, after intermittent fever, 521, 619; albuminous, toxicity of, 536; as an emetic, 690; as a vaccine, 74; average composition of the, 540; Oliver's test for bile in, 140.
Uroleucic acid, 188.
Urticaria pigmentosa, 291.
Uterine appendages, electricity *vs.* laparotomy in inflammatory affections of, 204; removal of, with unfavorable sequelæ, 389.
Uterine cough, treatment of, 691.
Uterine displacements, hysterorrhaphy in, 576.
Uterine fibroids, 371.
Uterine hemorrhage, electricity in, 62.
Uterus, abscess of, 436, 692; acquired atrophy of, 422; and tubes, primary tuberculosis of the, 107; as a candlestick, 540; cancer of, carburetted hydrogen in, 195; chloride of zinc in diseases of, 592; dilatation *vs.* divulsion of the cervix, 588; epithelioma of the body of the, 655; extensive laceration of the cervix, 655; fibroids of, complete abdomino-vaginal hysterectomy for, 181; fibroids of, treat-

ment of, by Apostoli's method, 10, 102, 253; fissure of the cervix, 565; flexions of, etiology, pathology, and treatment of, 347; inversion of, after somatic death, 460; misplacements of, due to disease of the appendages, 571; myoma of, 77; myoma of, electrolysis in the treatment of, 555; round ligaments of, value of the operation of shortening the, 514; rupture of the, 656; sarcoma of the cervix, 77; stenosis of the cervix, electricity in, 62; suspension of the, for prolapsus, 183; tubercular affections of the, 217.
Uvula, and epiglottis, functions of the, 393; cutting the, 661.

V

Vaccination, unsuccessful, and immunity against small-pox, 155, 180.
Vaccinator, a new, 719.
Vaccine, urine as a, 74.
Vagina, a woman without a, 486; cyst of, 161; occlusion of, 95.
Vaginal tampon, 178, 280, 411, 493.
Valgus, reflex, 334.
Van Arsdale, Dr. Henry, death of, 271.
Van Nüys, Dr. T. C., notice of book by, 517.
Varicocele, King's clamp in the treatment of, 12.
Vaseline, atomizer for warming and spraying, 111.
Vaughan, Dr. Victor C., notice of book by, 518.
Veeder, Dr. M. A., sudden death from distention of the stomach, 40.
Vegetarianism and cancer, 167.
Vein, entrance of air into a, 224.
Venereal warts, treatment of, 508.
Veratrum viride in diphtheria, 448.
Verdi's Hospital, 679.
Vermiform appendix, disease of the, 655.
Vertebræ, cervical, dislocation of, 377.
Vertigo, gastric, and ptomaines, 746; smoker's, 425.
Vesical tumor, spontaneous expulsion of, after perineal section, 481.
Vesico-urethral erethism in locomotive engineers, 495.
Vesico-uterine fistula, operation for, 519.
Vibration, muscular, rhythm of, in health and disease, 269.
Vigier's coryza powder, 643.
Viscera, traumatic displacement of, 663.
Vitreous, treatment of membranous opacities in the, 135, 238.
Vleminck's solution in the treatment of diphtheria, 703.
Vocal cords, restoration of the voice after destruction of the, 567.
Voice, restoration of, after destruction of the vocal cords, 567.
Volt, definition of, 61.
Vomiting, chronic, relieved by abdominal section and the breaking down of adhesions of the pyloric end of the stomach and of the duodenum, 620; of pregnancy, electricity in, 563; of pregnancy, rectal injections of carbolic acid in the treatment of, 175; of pregnancy, viburnum in, 680.
Von Bamberger, Professor, death of, 679.

W

Wading, the dangers of, 159.
Walker, Dr. James B., notice of book by, 517.
Warner, Dr. Frederic M., the sterilization of milk, 244.
Warts, treatment of, 28, 468; venereal, treatment of, 508.
Water, boiled, as an aseptic, 662.
Water-supply, additional, to New York City, independent of the Croton water-shed, 401.
Weather, the, and cholera infantum, 59.
Webster, Dr. David, a case of extraction of partially absorbed calcareous lens, complicated by synechia posterior, with resulting vision of $\frac{20}{20}$, 390.
Weigert, Dr. Louis, a new method of treating consumption by inhalations of hot dry air, 620.
Weigert's corrected method for staining fibrin in sections, 571.
Weir, Dr. Robert F., remarks on Whitehead's operation for hæmorrhoids, and on scraping out or erosion of carbuncle, 29.
Welch, Dr. Geo. T., toxicological effects of boracic acid, 531.
Wendt, Dr. E. C., letter from Freiburg, 193.
Wetherby, Dr. B. J., a woolly-headed child, 180.
What to do in emergencies, book notice, 516.
Whiskey not an antidote to rattlesnake poison, 479.
White, Dr. J. William, the antiseptic use of Malgaigne's hooks in transverse fracture of the patella, 503.
White, Dr. John Blake, a new urethrotome for close strictures of the penile urethra, 660.
Whitehead's operation for hæmorrhoids, 29, 47.
Whittling as a means of education, 512.
Whooping cough, bacillus of, 46; sulphurous-acid fumigations in, 215.
Wight, Dr. O. W., death of, 570.
Williams, Dr. E., death of, 485.
Williams, Dr. Hamilton, abscess of the left lobe of the liver—evacuation by incision into the abdominal wall—recovery, 704.
Wilson, Dr. John S., aphasia occurring during the secondary stage of syphilis, 179.
Winckel, Dr. F., notice of book by, 516.
Windsor, Dr. C., intracapsular fracture of the neck of the femur—patient able to walk with little deformity or lameness for three years—new disease then setting up, with great apparent shortening and deformity—death, 732.
Wintergreen, toxic dose of the oil of, 96.
Wister, Dr. Casper, death of, 757.
Witthaus, Dr. R. A., notice of book by, 516.
Women, and obscene literature, 112; and the study of medicine, 711; catheterization of, 277; physicians in medical societies, 246; students of medicine in Ireland in the eighteenth century, 172; the consequences of gonorrhœa in, 43.
Wool-fat, purified, 25.
Woolly-headed child, 180.
Word-blindness, 499.
Worms, intestinal, mineral waters in, 150; obstruction from, 182.
Worthington, Dr. J. M., the catheterization of women, 277.
Wright, Dr. Jonathan, a pathological condition of the middle turbinated bone, 264.
Writing-paper, blue-lined, injurious effect of, 397.
Würdemann, Dr. H. V., the tea-leaf eye, 417.

Y

Yellow fever, 463; alkaline treatment of, 428; epidemic, 295; epidemic, origin of the, 680; history of, 523; hospitals, artificial cold for, 608; microbe in, 183, 426; researches relating to the etiology of, 369; so-called specific germ of, 548.

Z

Zaleski's chemical lung test, inefficiency of, 95.
Zittmann's decoction in syphilis, 84.
